## **December 2012**

*Prepared for CNMI DEQ and NOAA as part of the Northern Mariana Islands Coral Reef Initiative with The Nature Conservancy, Pacific Marine Resources Institute and the CNMI Division of Fish and Wildlife as collaborating agencies.*

## **Acknowledgments**

This work was co-led by the first and second authors. The investigators and contributors thank WPCRI and UoG for their financial support of parts of the project on behalf of the team and collaborating managers. The fieldwork and some of the contract work and salaries for the project and project time was supported by CNMI Coral Reef Initiative Funding from NOAA's Coral Reef Conservation Program, Senator Gregorio Kilili Sablan Funding in CNMI, and research funds provided by CRIOBE/IRCP of Moorea, French Polynesia. The following people all played a role in completing the fieldwork: Fran Castro, Kaitlin Mattos, John Iguel, and Aric Bickel from CNMI DEQ, Sam Sablan from MINA, Jess Omar, Michael Tenorio, Trey Dunn and the Enforcement and Permitting Section of CNMI DFW, and Rebecca Skeeel from CNMI CRMO. Logistical boat support was provided by Hideyuki Kaya, Anthony Tenorio, Fons Ngirmeril, Simon Aldan Sebuu, and Ian Carr. Figures were developed in collaboration with D. Tracey and the work greatly benefited from discussions with Nick Graham.

## Executive Summary

Coral reefs are severely threatened by climate change and human activities that challenge the natural resilience of these systems to resist and recover from disturbances. Managers, conservationists and policymakers are all working to tackle the challenges of giving reefs the best chance of coping with projected climate change impacts. Recently, reef resilience has received added research attention because disturbance frequencies are expected to increase under climate change scenarios. For this reason, many have been working to develop frameworks that enable reef resilience to be assessed and compared among sites. Identifying sites with high resilience potential can inform a range of management decisions to support and maintain coral reefs. Presently, a framework has been published that suggests 11 variables be evaluated to compare the resilience potential of coral reef sites. These are: coral diversity, bleaching resistance, recruitment, herbivore biomass, macroalgae cover, temperature variability, nutrient input, sedimentation, fishing access, coral disease, and anthropogenic physical impacts (McClanahan et al. 2012).

This report presents the results of the first field-based implementation of the McClanahan et al. (2012) framework from 35 sites around Saipan. This applied research was funded by the NOAA Coral Reef Initiative and is a collaboration of representatives of the following agencies: CNMI DEQ, NOAA, DFW, CRM, PMRI, and TNC. The resilience scores calculated are the average of the scores for 9 variables included in the analysis (the variables above minus coral disease and anthropogenic physical impacts, which were not observed). The relative categories high, medium and low were used to describe the scores for all independent variables and the resultant resilience scores. The report presents the results of the resilience analysis, including resilience rankings and maps, and presents suggestions for managers as well as our working group's plans to continue and advance the research presented here in 2013/14.

23 sites were found to have high relative resilience; 9 sites have medium, and 3 have low. Principal Components Analysis revealed that all 9 variables contributed to differentiating the sites but rankings were most strongly driven by coral diversity, bleaching resistance and macroalgae cover. Without exception, sites with the highest resilience, relative to other sites surveyed, have high coral diversity, high bleaching resistance and low macroalgae cover. Low resilience sites have low coral diversity, low bleaching resistance, and high or at least some macroalgae cover. High and medium resilience sites are located throughout all of Saipan's reef habitats while the low resilience sites are all in the Saipan lagoon.

Some of the suggestions for managers presented include: considering additional management and enforcement at four of the top ten high resilience sites that are not currently in protected areas, giving the sites with high resilience and high coral cover special attention to facilitate tourism opportunities, and monitoring and maintaining herbivory at sites especially vulnerable to coral bleaching.

Scoring for all independent variables and the final resilience scores are all relative to the sites surveyed only. Thus, the data can be re-analyzed and assessed when CNMI-wide results and recommendations become available in 2014 following surveying around Rota and Tinian. Follow-up work to that presented here is being planned and is described in the report's concluding 'Next steps' section. The planned advancement of this work has already been partially funded. This applied research from Saipan is amongst only a few examples of operationalizing resilience as a concept to inform tractable informed management decisions. This work will continue to benefit from the high level of engagement amongst local and collaborating international agencies that has been characteristic of the project thus far.

# 1. Introduction and objectives

Climate change is now widely regarded as the single greatest long-term threat to coral reef ecosystems; the world's most diverse marine ecosystems (review in Hoegh-Guldberg et al. 2007). Climate change impacts projected for reefs include a greater frequency and severity of coral bleaching events. These 'mass' bleaching events are caused by anomalously warm sea temperatures and have already impacted many of the world's reefs (reviews in Hoegh-Guldberg 1999, and Hoegh-Guldberg et al. 2007). Other climate-related impacts include increased ocean acidification (Anthony et al. 2011). As the oceans absorb more and more carbon dioxide, they acidify, which weakens coral skeletons, reducing growth rates and increasing susceptibility to damage from storms (review in Kleypas et al. 2006). Further, severe tropical storms are expected to increase in frequency and sea levels are rising (IPCC 2007). Changed rainfall and ocean circulation patterns are also expected on a range of spatial scales. These changes could increase freshwater input to some coral reef areas and affect source-sink recruitment dynamics for corals, other reef invertebrates, and reef-associated fish (Munday et al. 2009).

Despite the severity of the threats posed by climate change, for most reef locations stress caused by human activities is an even more imminent concern (Burke et al. 2011). Coastal development, dredging, construction, and coastal land management and use all affect water quality on reefs (Burke et al. 2011). The dominant framework builders on reefs, the stony corals, have to compete for space and light with algae. Algae grow faster than corals, especially in nutrient-rich waters, so algae sometimes out-competes corals when water quality is poor (McCook 1999). This is a competition made tougher for corals as coastal populations target and extract the herbivorous fish that help control algal growth (McCook 1999). Reefs have always faced natural and man-made disturbances and have always been dynamic systems (Nystrom and Folke 2001). Now though, increasing levels of anthropogenic stress and the projected effects of climate change pose unprecedented challenges to the resilience of reef systems (review in Hoegh-Guldberg et al. 2007). Resilience is the capacity to resist and recover from disturbances to maintain or return to a state that provides the goods and services upon which, for reefs, hundreds of millions of people depend (Resilience Alliance). That reef resilience is being challenged is supported by observations from around the world of declining coral cover on reefs in recent decades (examples; Bruno and Selig 2007; De'Ath et al. 2012).

Managing coral reefs in the face of local and global-scale stressors requires tackling the issues from several angles (Marshall et al. 2006). The condition of a coral reef can be likened to a patient with acute and chronic illnesses and both need to and are being addressed (Anthony and Maynard 2011). Policymakers and others are working to reduce greenhouse gas emissions and slow the rate of climate change. At the local-scale, managers and conservationists are working to support the resilience of reefs by reducing anthropogenic stress (examples: Maynard et al. 2010, 2011). Reef managers have a range of tools at their disposal to reduce stress. Tools such as protected areas reduce stress at a smaller scale, while others like watershed restoration efforts can

affect large areas of reef habitat. Though most managers have at least some options for reducing stress on reefs, the areas to be managed are often large and resources to establish and enforce actions to reduce stress on reefs are usually scarce. For this reason, many managers benefit from knowing the actions they could take, and the areas they could implement these actions, to maximize their capacity to support reef resilience (Maynard et al. 2010).

Researchers have been working to identify the key characteristics of resilient reefs and through collaboration with managers and conservationists are developing ways to evaluate these 'resilience indicators'. In the most recent review, McClanahan and colleagues (2012) present a resilience assessment framework based on 11 key indicators that an expert panel believed to be of the greatest importance, and have the strongest empirical evidence (as conferring resistance or resilience).

“Identifying the top-ten ranked factors for resilience independently for perceived importance and scientific evidence, showed some overlap in factors, but produced a total list of 13 factors (Table 2). From this list, we only included factors that were considered feasible to assess (average feasibility scores .5), which resulted in a final list of 11 key factors for resilience management and conservation, ranging from the presence of stress-resistant corals to areas of reduced fishing pressure. Using only this final list of 11 key factors, we developed a site-selection framework for management.” – From McClanahan et al. 2012

The 11 recommended indicators are thus not necessarily *all* the indicators that may drive resilience potential at a site and differences in resiliency among sites. Rather the 11 are among the most important and have the greatest scientific evidence as influencing resilience. Further, the relative importance of each indicator to a final resilience score is diluted with each indicator added. We use the 11 recommended indicators here and recognize that other indicators could be important in Saipan and that this field of research is still growing and advancing. Definitive global or regional guidance for reef managers in the area of assessing resilience potential in the field has yet to become available. The 11 indicators recommended in McClanahan et al. 2012 and used here are: coral diversity, recruitment, bleaching resistance, temperature variability, herbivore biomass, macroalgae cover, nutrient input, sedimentation, fishing pressure, coral disease and anthropogenic physical impacts. The relative resilience potential of reef sites can be calculated and compared by measuring and assessing the recommended indicators at surveyed sites.

The research and work presented was conceptualized by some in the team at a workshop chaired by The Nature Conservancy in Guam in 2009. The aim initially was to develop and improve on the capacity within CNMI to respond to coral bleaching events. This became the basis of a proposal funded by the Coral Reef Initiative of NOAA to gather baseline information from reefs rarely or never visited around Saipan. The vision for the work expanded during the funding process. Collecting baseline information from infrequently visited sites as well as sites that have never been surveyed remained a priority. In total, 21 sites not visited annually by the Marine

Monitoring Team of CNMI's Division of Environmental Quality were surveyed (35 sites in total). In addition to collecting baseline information, the resilience assessment framework put forward by McClanahan et al. (2012) was completed. Undertaken in March of 2012, this was the first field-based implementation of this resilience assessment framework. Specific suggestions were developed on the back of the results to support reef resilience in CNMI.

The four specific objectives of the applied research we have conducted and will continue are:

- 1) To assess and measure the benthic community composition, key resilience indicators and anthropogenic stress at reef sites throughout CNMI.
- 2) To determine the relative resilience potential of sites we survey, to map and spatially interpolate the results, and to present findings in combination with assessments of combined anthropogenic stress.
- 3) To develop defensible suggestions for managers as action options to consider such that the natural resilience of reefs in CNMI can be supported and so that resilience can increasingly inform local management decisions.
- 4) To share our results with the broader scientific and management community in a two-way exchange such that others can benefit from our efforts and lessons learned and that our work can benefit from the efforts of others.

Objectives 1 and 2 are covered in the methods and results, and the report concludes with overviews of Objectives 3 and 4. As above, work towards all objectives is ongoing.

## **2. Methods**

### *2.1 Data collection*

Eleven variables were included in the resilience analysis, based on the site selection framework described in McClanahan et al. (2012). Data were collected and compiled on all 11 in Saipan from March 1 to May 20 of 2012 at a total of 35 sites (Fig. 1). Appendix 1 contains the survey site coordinates and Figure 1 shows the site locations. Survey and assessment methodologies used for each variable are described below with variables categorized as having been assessed in the field or via a desktop analysis. In addition to the 11 variables included in the resilience analysis, benthic community composition was assessed, using 3 x 50 m point-intercept transects (0.5 m intervals, 100 points per transect) at each site. In addition to the methods used to assess coral community structure (described below), a list of all species seen at the site was recorded. The resultant species list was used to tally all coral species seen at each site that were among the 82 species petitioned for endangered species listing in 2009 and the 66 of those proposed for listing by NMFS in December of 2012.

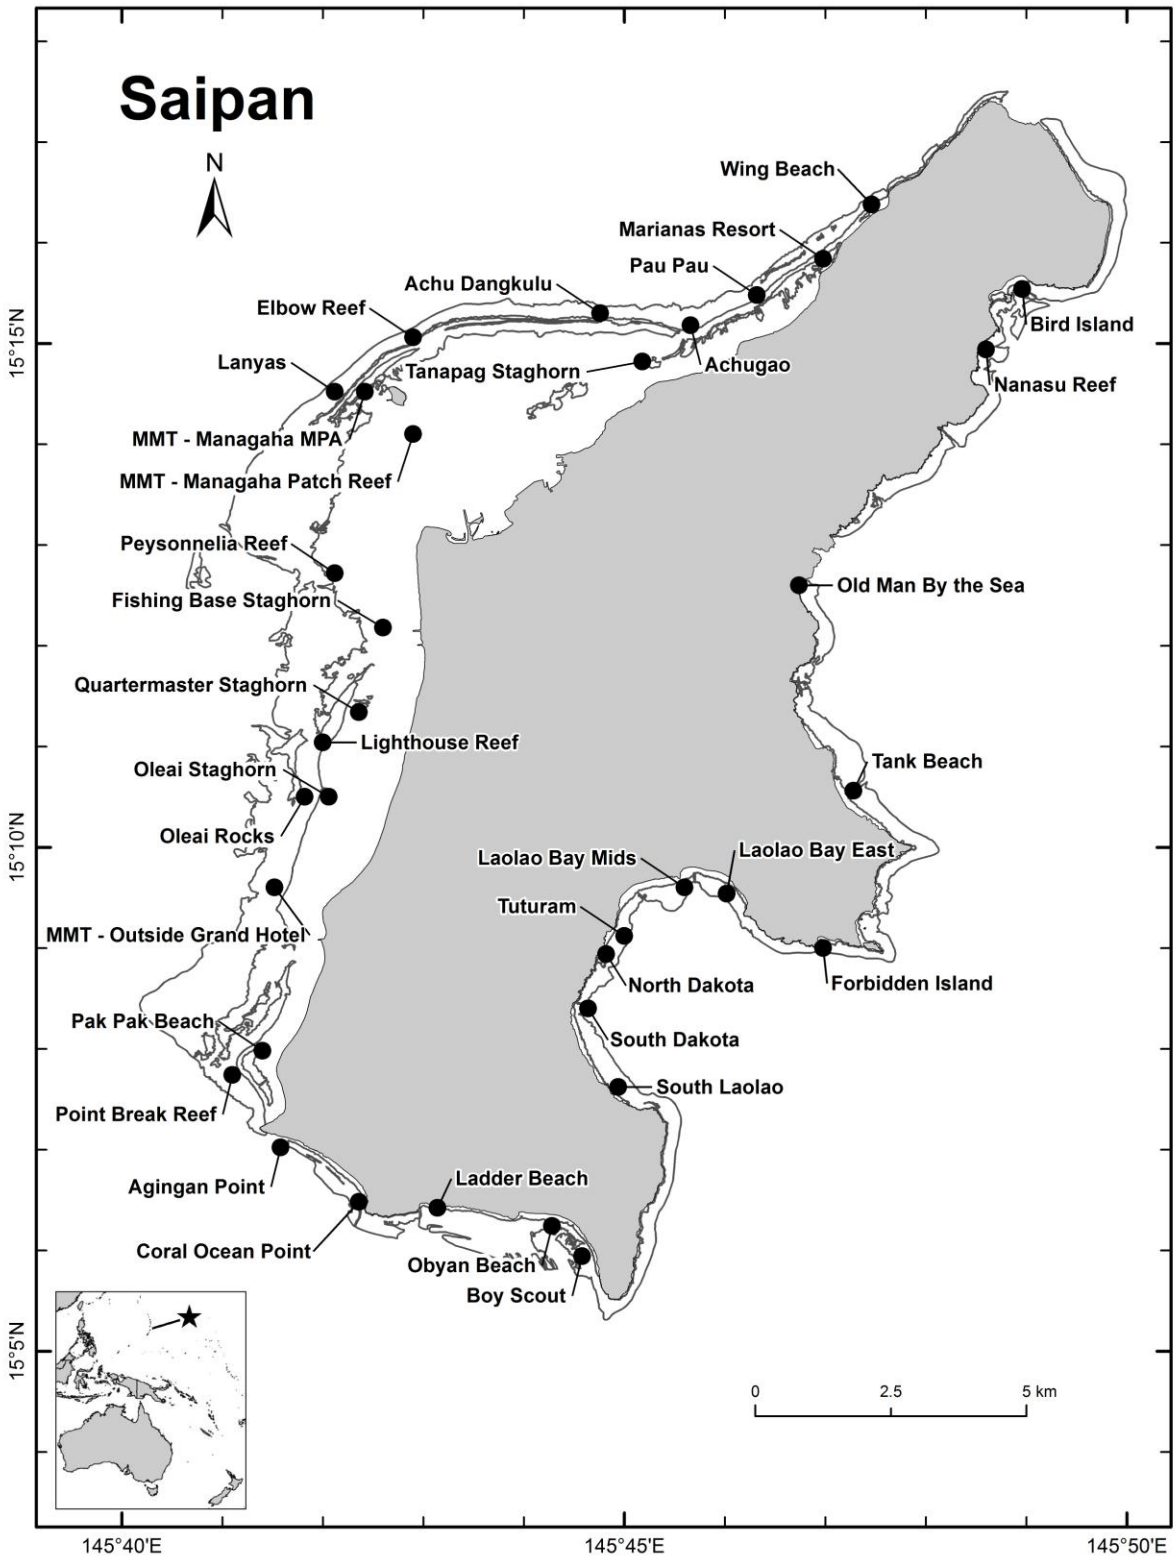

Fig. 1. Locations of the 35 sites surveyed between March and May of 2012 for the resilience analysis.

## 2.2 Fieldwork; variables measured

Variables assessed in the field include: coral diversity, recruitment, bleaching resistance, herbivore biomass, macroalgae cover, coral disease, and anthropogenic physical impacts (i.e., anchor and fin damage). Survey methodologies and units for each are described below.

### *Coral diversity*

All corals were identified to species within 16, 0.25 m<sup>2</sup> quadrats haphazardly tossed along three 50 m line transects laid sequentially with 2-10 m gaps along the same depth (8-10 m for reef sites, 2-4 m for lagoon sites). A checklist of species encountered at the site was made (species richness), and the abundance of each species encountered in the quadrat tosses was derived. Simpson's Index of Diversity (unitless, ranging from 0 to 1) was calculated. This index asks the likelihood that two randomly sampled individuals will **not** be of the same species; the greater the likelihood (closer to 1) the higher the diversity. The formula for Simpson's Index is given below, where  $n$  = the total number of organisms of a particular species, and  $N$  = the total number of organisms of all species observed.

$$D = \frac{\sum n(n-1)}{N(N-1)}$$

### *Recruitment*

The geometric mean (two longest lengths averaged) of all corals within 16, 0.25 m<sup>2</sup> quadrats (see Coral diversity for transect information) was calculated. Recruits were considered to be corals with a geometric mean <4cm. The density of recruits was calculated for each site and became the final recruitment measure; sum total of recruits across all quadrats divided by 4 (for meters) yielding 'recruits/m<sup>2</sup>'.

### *Bleaching resistance*

Every coral species identified during the surveys was given a bleaching susceptibility score from 0 to 10; the higher the score the more susceptible the species to thermally-induced bleaching. Rankings were produced using an expert focus group that reviewed the literature, as well as data from the only well documented bleaching event in Saipan – the 2001 event (see Appendix 2). Species with a susceptibility score of 4 or less were considered resistant for this analysis. The proportion (%) of the community made up of bleaching resistant corals was then calculated for each site. The community of corals at each site was considered to be the species identified using the quadrats described for 'coral diversity' above.

### *Herbivore biomass*

Three 3-minute 5-meter radius stationary point counts (SPC's) were performed along each of three different 25m transect lines at each site, for a total of nine SPC's at each location. The transect lines and SPC's were set over hard bottom habitat at a depth of approximately 30-feet. SPC areas never overlapped and there were typically 5 to 10-meters of space between each count. The SPC counts were performed prior to any other activities at each site to minimize diver influence and most counts were done while rolling out the initial transect lines which provided a precise distance with which to reference SPC boundaries. All herbivorous fish and all other fish larger than 10 cm in body length were identified to species, and their length was estimated to the nearest cm. The weight of each fish in grams was then calculated using the standard equation –  $W = aL^b$ , where  $W$  is weight,  $L$  is length, and  $a$  and  $b$  are coefficients specific to each species. The coefficients used were sourced from NOAA's Coral Reef Ecosystem Division, are up-to-date and are mostly standard across the globe for all of the fish species identified. Species were classified as herbivores using IUCN's classification for these species (Green and Bellwood 2009) and when not available were classified as herbivores if known to be herbivorous in Saipan and/or elsewhere. Herbivore biomass was calculated for each SPC at each site following summing, and converting to kg/100 m<sup>2</sup>. The average herbivore biomass was used here and is based on averaging across all nine SPCs.

### *Macroalgae cover*

Three 50 m point-intercept transects were laid as described in the Coral diversity section. At 50 cm intervals (100 per transect, 300 per site) the benthos was categorized as live coral, dead coral, soft coral, sand, rubble, crustose coralline algae (CCA), pavement (bare hard substrate without CCA), macroalgae, turfing algae, and other invertebrates (i.e., sponges and sea stars). Macroalgae cover was calculated as the average (across transects) percent of the points identified classified as macroalgae.

### *Coral disease*

All observations of coral disease were to be identified and described within 1 meter either side of the three 50-m transects (see Coral diversity section), so three 100 m<sup>2</sup> belt transects. ***No coral disease was identified or described at any of the sites during these surveys so coral disease is not included in the resilience analysis.*** At many sites non-normally pigmented tissue was seen on many *Porites* spp. (pink and blue tissue mostly), which is known to be an inflammatory-like response caused by interactions between the coral tissue and many organisms (see Palmer et al. 2008). This is not a disease per se, but warrants ongoing attention.

### *Anthropogenic physical impacts*

***All instances of anchor or diver damage were to be documented, described and photographed but no such damage was observed at any of the sites.***

In the field, the SPC surveys for herbivore biomass were completed first by a 2-diver team over the course of 1 hour. The quadrat portion of the benthic surveys (for bleaching sensitivity, and species diversity) were completed by one in the first diver team within sight but behind the diver counting and identifying fish. A second two-diver team entered the water 45 minutes after the first team to conduct the remaining benthic surveys. Total time at each site ranged from 90-120 minutes.

### 2.3 Desktop; variables assessed

Variables assessed using remote sensing and GIS software include: temperature variability, nutrient input, sedimentation, and fishing access. The methodologies used to assess each are described below.

**Temperature variability:** Observed sea surface temperature (SST) data for the period 1982-2010 was obtained from NOAA AVHRR Pathfinder Version 5.2, which has a resolution of 4 km (Casey et al. 2010). The data was quality screened; only data with a quality flag of 4 or greater was used. For each pixel the maximum monthly mean (MMM) was calculated – this is the month of the year with the highest average temperatures during the 28-yr period. The month with the MMM and one month either side was considered the 12 week summer period. During similarly stressful events, reefs with high variability in temperatures during the summer period have been observed to bleach less severely than reefs with low temperature variability (recent example in Guest et al. 2010). It is unknown, however, how variable temperatures need to be for an increase in temperature tolerance to be noted. Variability is calculated here as the standard deviation of the summer temperatures.

**Pollution and Sedimentation Proxies:** A proxy for pollution loading was developed using geographic information system (GIS) layers pertaining to watershed size, topography, and discharge flow direction. Digital elevation models (i.e., topographic data) were first used to define watershed boundaries and likely flow patterns for discharge waters. Subsequently, each site was attributed to an adjacent watershed. The proxy for pollution loading was then calculated as a continuous variable by measuring the watershed size. Thus, it was assumed that watershed size was a disproportional contributor to overall pollution loading. A proxy for sedimentation was generated by incorporating United States Forest Service GIS layers pertaining to land use (<http://www.fs.usda.gov/r5>). Land use categories were simplified into three classes: 1) barren land/urbanized vegetation/highly developed, 2) shrubs, and 3) vegetation with canopy cover. The sedimentation proxy was estimated by the percent cover of class 1 within each watershed.

**Fishing access:** Several proxies were considered to accurately depict fishing pressure: 1) wave exposure, 2) distance to shoreline access, 3) distance to nearest large population center, and 4) number of people in the nearest population center. We examined several combinations of these variables for their ability to match an expert survey on perceived differences in relative fishing pressure, whereby local fishers and

fishery managers were asked to evaluate fishing pressure at our survey sites as being ranked low, medium or high. Our preliminary analysis found that wave exposure alone most closely matched the results of the manager's survey and created a direct rank match for approximately 70% of the sites. When we ran the same comparison including distance to shore or population centers the results were a much poorer match, with less than a 50% of the sites lining up with the manager's survey in both cases. Most sites were within short drives from population centers and short swims from shore which could explain why attempts to add those metrics created such deviation from the manager's survey. Reef fishing is driven by accessibility, which is mostly driven by average wave height and wave heights are higher on the eastern shore due to prevailing winds. Fishing 'access' from wave height alone is thus used here as a proxy for fishing pressure.

Wave exposure was estimated by using long-term wind datasets, and GIS layers pertaining to varying angles of exposure for each survey site. For each site, fetch (i.e., distance of unobstructed open water) was first estimated for each site within 16 quadrants (i.e., 0 to 360 degrees, equally distributed into 16 bins). Fully developed sea conditions were considered if unobstructed exposure existed for 20 km or greater. Ten-year long-term windspeed averages were calculated from Saipan airport data ([www7.ncdc.noaa.gov/](http://www7.ncdc.noaa.gov/)), and used as inputs to calculate wave height following Ekebom et al. (2003). Specifically, mean height was calculated by:

$$H_m = 0.019 U^{1.1} F^{.45} \quad (1)$$

$H_m$  is the wave height (m) for each quadrant,  $U$  is the windspeed at an elevation of 10m, and  $F$  is the fetch (km). Windspeed corrections for varying elevations were made following Ekebom et al. (2003). Last, wave height was converted to energy following:

$$E = (1/8)\rho g H^2 \quad (2)$$

Where  $\rho$  is the water density (kg/m<sup>3</sup>),  $g$  is the acceleration due to gravity (9.81 m/s<sup>2</sup>), and  $H$  is the wave height (m). This process resulted in continuous data on wave exposure (in terms of wave energy), used here to describe 'access' to the fishery.

Fishing access was considered to be '0' for all protected areas, irrespective of wave energy at the site, thus giving no-take MPA sites the best possible score (1) to account for the restricted access and perceived enforcement.

## 2.4 Data analysis

### *Resilience potential*

Nine variables were used to calculate resilience potential - coral diversity, recruitment, herbivore biomass, bleaching resistance, temperature variability, macroalgae cover, nutrient input, sedimentation and fishing access. To calculate resilience potential (the final output), values for each variable were first anchored to the maximum value for the

variable among the pool of sites and then normalized to a 0 to 1 scale. For each variable, the site with the maximum value is given a score of 1. All other values for that variable - all of the sites with less than the max value - are normalized to the score of 1 by dividing by the maximum value. For example, if the maximum bleaching resistance value is 64%, the site with 64% receives a 1 and the site with 60% receives a 0.94 (or 60 divided by 64). Anchoring values to the max value helps make clear exactly how different one site's value is from others.

To produce a composite score, the scale for the anchored and normalized scores must always be the same (0-1) and be uni-directional; i.e., here, a high score is always a good score. This requires subtracting the anchored score from 1 for macroalgae cover, nutrient input, sedimentation and fishing access since high levels of these are a negative rather than a positive for reef resilience. 1 minus the anchored score results in the same 0 to 1 scale and ensures that the sites with low values for macroalgae cover, nutrient input, sedimentation and fishing access receive the best possible scores (i.e., 0% macroalgae cover would receive a 1).

Normalizing to a standard scale ensures the scores can all be combined into the composite resilience score, which is the average of all of the anchored and normalized scores. That score is one final 'resilience potential score'. An alternate is also produced by using the anchoring and normalizing procedure again whereby the site with the highest resilience score receives a 1 and so on. Both values are shown in summary tables. Sites are ranked from highest to lowest anchored resilience score. Rankings, from 1 to 35 – are the numbers used to identify the sites throughout all of the results tables and on all of the mapping outputs. Sites with an anchored resilience score of 0.8 to 1 are considered to have high (relative) resilience potential, 0.6-0.79 medium, and <0.6 is low; these are green, yellow and red, respectively, in the relevant mapping outputs. These same ranges are used to describe high, medium and low scores for all of the variables used in the resilience analysis except macroalgae cover, nutrient input, sedimentation and fishing access. For those four, high scores or good scores are higher than 0.4 (equivalent to 1-0.6), medium scores are 0.21-0.4, and low scores are 0-0.2 (equating to 1 minus 0.8-1).

A principal components analysis (PCA) was undertaken to test whether differences between sites in final resilience scores are consistently driven by a few rather than all of the variables examined.

Resiliency scores for sites are not indicative of the health or condition on their own. In the framework used, a site can have a high resilience score relative to other sites due to a range of different combinations of high, medium and low scores for the variables. Further, state variables likely to be useful in assessing condition, like coral cover, are not included. Information on condition at the survey sites is presented in the results in the form of current levels of anthropogenic stress and Appendix 3 describes the benthic community composition at the survey sites.

### *Anthropogenic stress*

A composite score was produced for anthropogenic stress by averaging the anchored scores for fishing access, nutrient input and sedimentation. For consistency, such that the composite score for resilience potential can be calculated, high scores are good scores for these variables, so a high score equals low stress. As with resilience potential, scores from 0.8 to 1 are high scores or good scores (low stress), 0.6-0.79 medium, and scores of <0.6 are low and equate to high stress. The larger numbers signifying low stress is counterintuitive and an unfortunate effect of needing all anchored scores to be uni-directional for a composite score to be produced. The figure captions help with interpretation of the maps that describe the anthropogenic stressors and the colors used remain intuitive in that red denotes the sites with high stress.

### *Mapping outputs*

Maps have been produced using ArcGIS for resilience potential, anthropogenic stress, and for each of the nine variables. Spatial interpolation of the resilience analysis results was completed using the kriging process in ArcGIS, excluding the lagoon sites, which are portrayed as circular areas with ~500 m diameter. Nearest neighbor results are used for the interpolation, except in cases where the nearest neighbor is on the other side of the island (i.e., Bird Island). Interpolation results for resilience potential are contained to known reef area based on locally sourced habitat maps held by CNMI DEQ and PMRI.

Anchored scores are presented on the maps as 0 to 100 (to reflect percentage of max value) for ease of interpretation, but are from 0 to 1 in Table 2.

## **3. Results and Discussion**

Results for the nine variables used in the resilience analysis are described first, then the resilience analysis and kriging outputs, followed by a summary of benthic community composition at the survey sites. The section concludes with a summary of the coral species petitioned for endangered species listing in 2009 and the 66 of those proposed for listing by NMFS in December or 2012.

### **3.1 Individual variables**

For each of the individual variables included in the resilience analysis, all of the following are described and presented: the maximum value, the minimum value, the range, the number of sites with high (relative, see methods), medium and low scores, and any evident spatial patterns in the data. Bracketed [ ] numbers refer to final resilience rankings out of 35 and form the site labels on all maps shown.

### 3.1.1 Coral Diversity

The maximum Simpson's Index of Diversity value is 0.96 at Ladder Beach [21], Coral Ocean Point [25], Elbow Reef [23], and Tank Beach [31], and the minimum value, 0.0, at Fishing Base Staghorn [35]; a range of 0.96 (Table 1). The great majority of sites surveyed (31 of 35) have high relative coral diversity, 1 has medium (Oleai Staghorn [24]), and 3 have low relative diversity (Marianas Resort [33], Quartermaster Staghorn [34] and Fishing Base Staghorn [35]). The large range in diversity values found (Fig. 15, Table 1) is due to differences in the coral community compositions between some of the lagoon sites and the outer reef sites. The Three sites with the three sites with low relative diversity are all lagoon sites (Fig. 2).

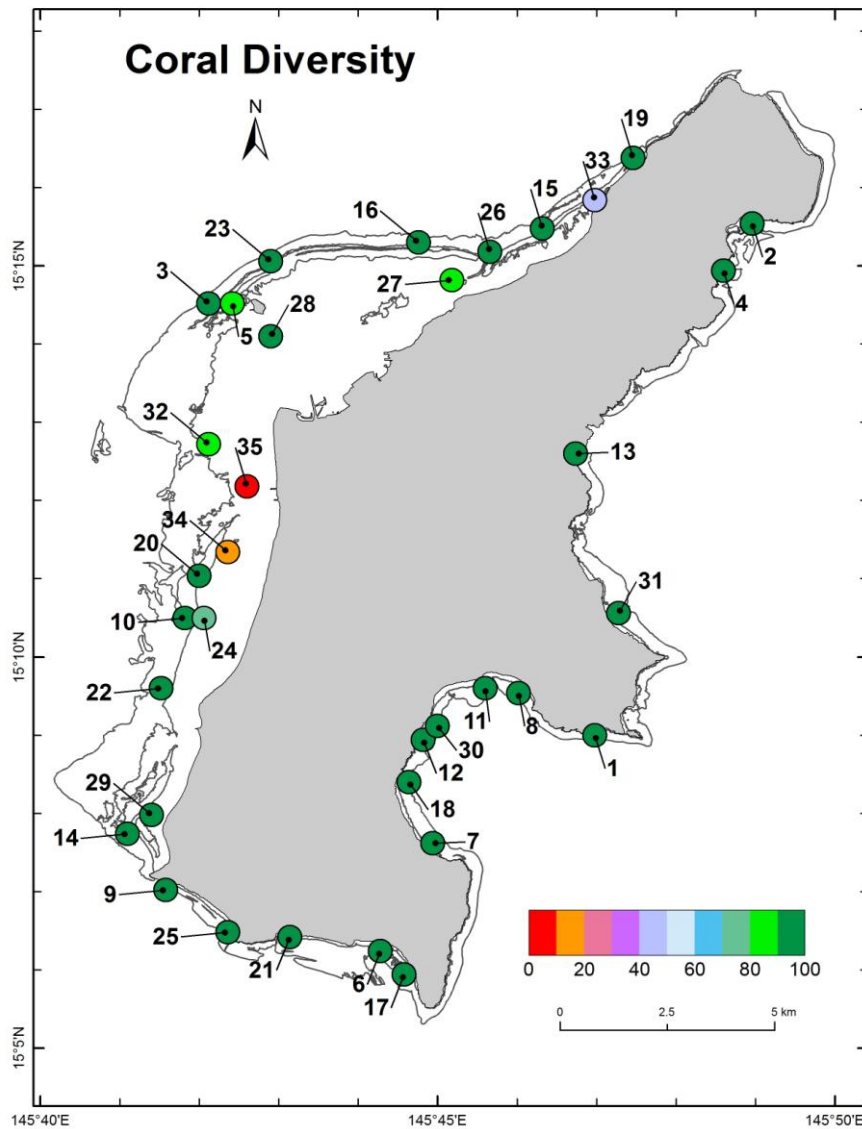

Fig. 2. Anchored coral diversity (Simpson's Index of Diversity) scores for the survey sites.

*Note on maps: From here forward, number labels on the maps refer to resilience rankings (Table 1). The ten-bin color bar forming this legend represents the anchored score as 0 to 100 (instead of 0-1 as in Table 2), to reflect the percentage of the max value across surveyed sites.*

### 3.1.2 Recruitment

The highest recruit density was found at LaoLao Bay East [8], 14.31 recruits/m<sup>2</sup>, and the lowest at Fishing Base Staghorn [35] where no recruits were observed. In the case of coral diversity (section 3.1.1) nearly all (31 of 35) sites had scores within 20% of the maximum value. In contrast, recruit densities observed at the survey sites are spread throughout the 0-14.31 recruits/m<sup>2</sup> range (Figs. 3 & 14, Table 1). Three sites have high relative recruitment: LaoLao Bay East [8], Agingan Point [9], and Obyan Beach [6] (Fig. 3). 13 sites have medium recruitment and 19 sites have low recruitment. Spatial patterns in recruit densities are weak; recruit densities are generally lower at lagoon sites and highest in the southern outer reefs and parts of LaoLao Bay (Fig. 3). Recruits (geometric mean <4 cm) are the most common coral size class observed when all sites are pooled (Fig. 4); recruits were observed within sampling quadrats as commonly as all four of the largest coral size classes (8-16, 16-32, 32-64 and > 64 cm) combined (Fig. 4).

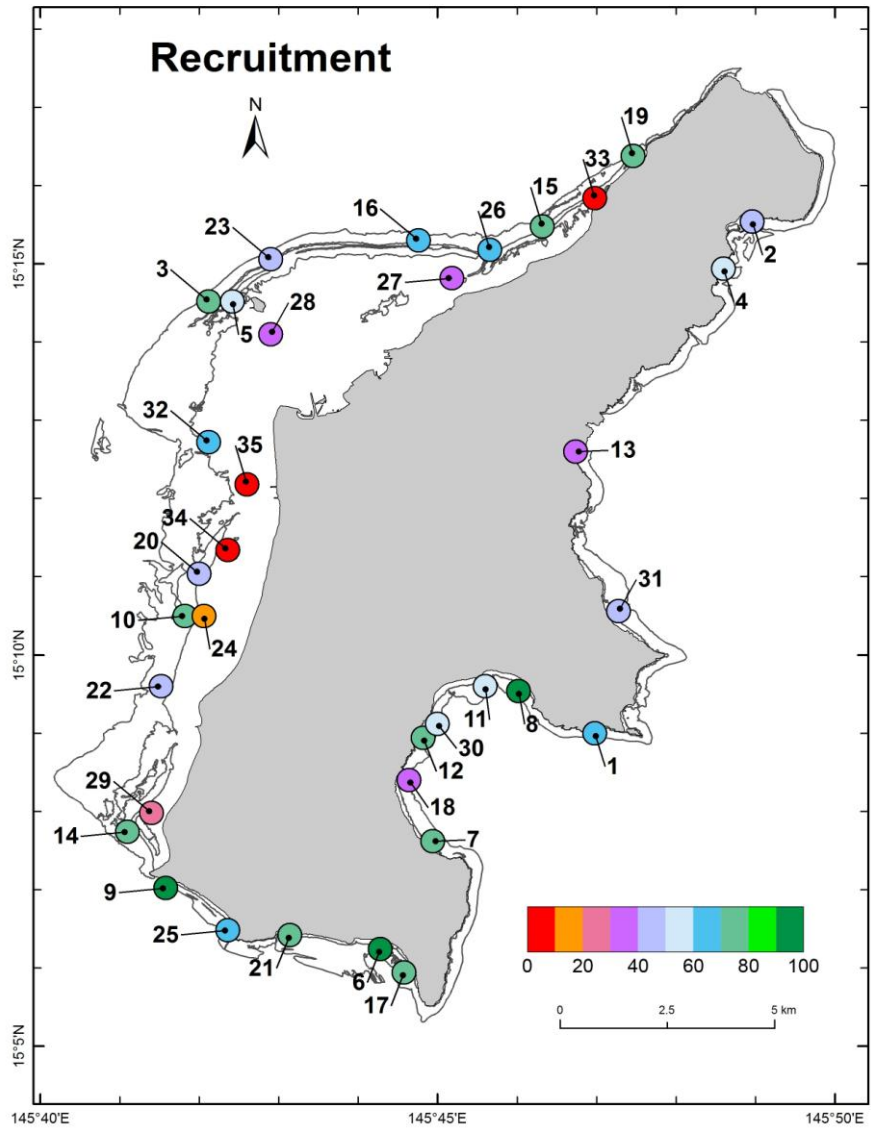

Fig. 3. Anchored recruitment scores for the survey sites.

Fig. 4. Size-class frequency histogram of coral colonies observed within sampling quadrats with all survey sites pooled.

### 3.1.3 Bleaching Resistance

The three highest bleaching resistance values (% of coral community) are all at lagoon sites with coral communities of medium diversity (Fig. 2): Oleai Staghorn (88.46% [24]), Peysonnelia Reef (85.95% [32]), and Tanapag Staghorn (82.67% [27]) (Fig. 5, Table 1). The three lowest bleaching resistance values are also at lagoon sites and are the three sites with the lowest coral diversity: Quartermaster Staghorn (20% [34]), Marianas Resort (20%, [33]), and Fishing Base Staghorn (0% [35]). Therefore, the full range of bleaching resistance seen among the 35 survey sites can be found in the lagoon with some sites highly susceptible to bleaching and some amongst the most bleaching resistant (Fig. 5). There are 9 sites with high relative bleaching resistance, 19 with medium, and 7 with low (Fig. 15, Fig. 5). Spatial patterns in bleaching resistance are weak excepting that all of the sites with high relative bleaching resistance are in the lagoon and LaoLao Bay. Most outer-reef sites have medium bleaching resistance (Fig. 5).

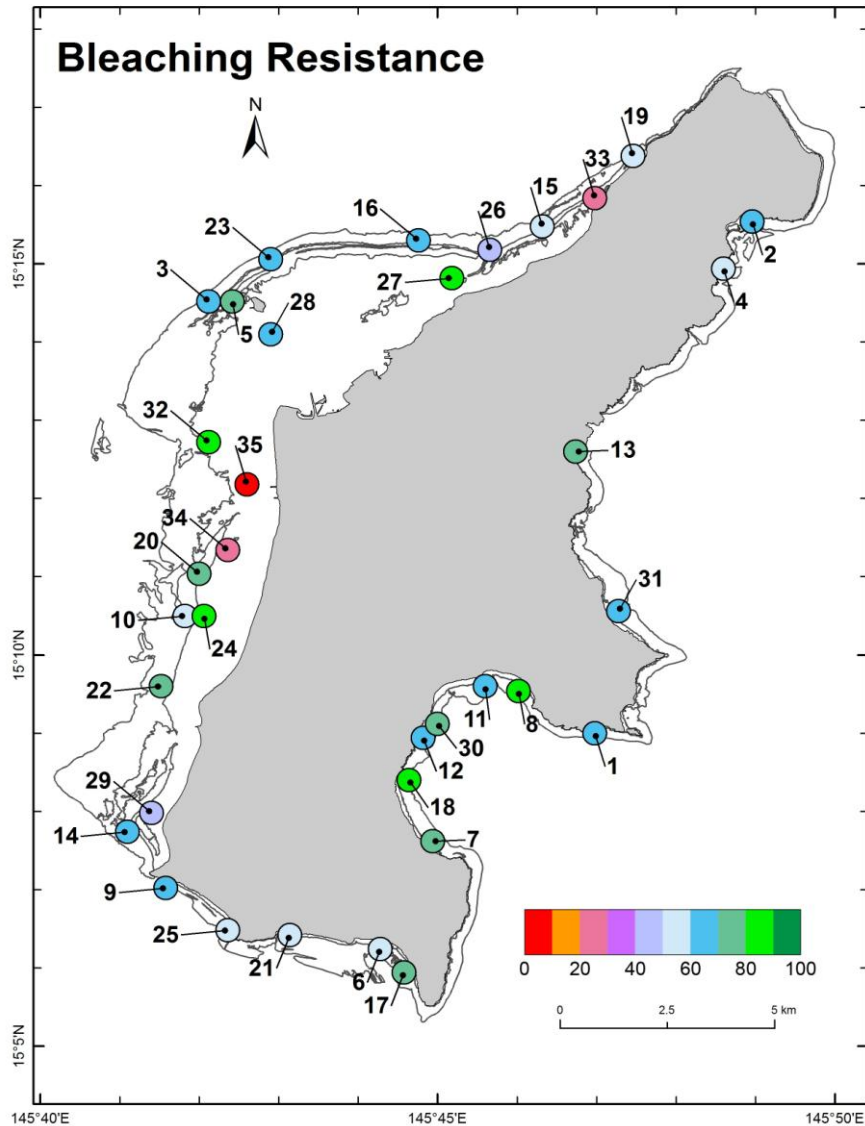

Fig. 5. Anchored scores for bleaching resistance for all survey sites.

### 3.1.4 Temperature variability

Summertime temperature variability, as measured by the standard deviation in temperatures during summer months from 1982-2005, is roughly 1°C for all survey sites (Table 1). The site with the highest summertime temperature variability is Nanasu Reef [4] with 0.98 °C, but the lowest is only 0.05 °C lower: Old Man By the Sea (0.94 °C [13], Fig. 15). All sites have high relative temperature variability; summertime temperatures vary no more or less at lagoonal sites than outer-reef or the more exposed eastern sites (Fig. 6).

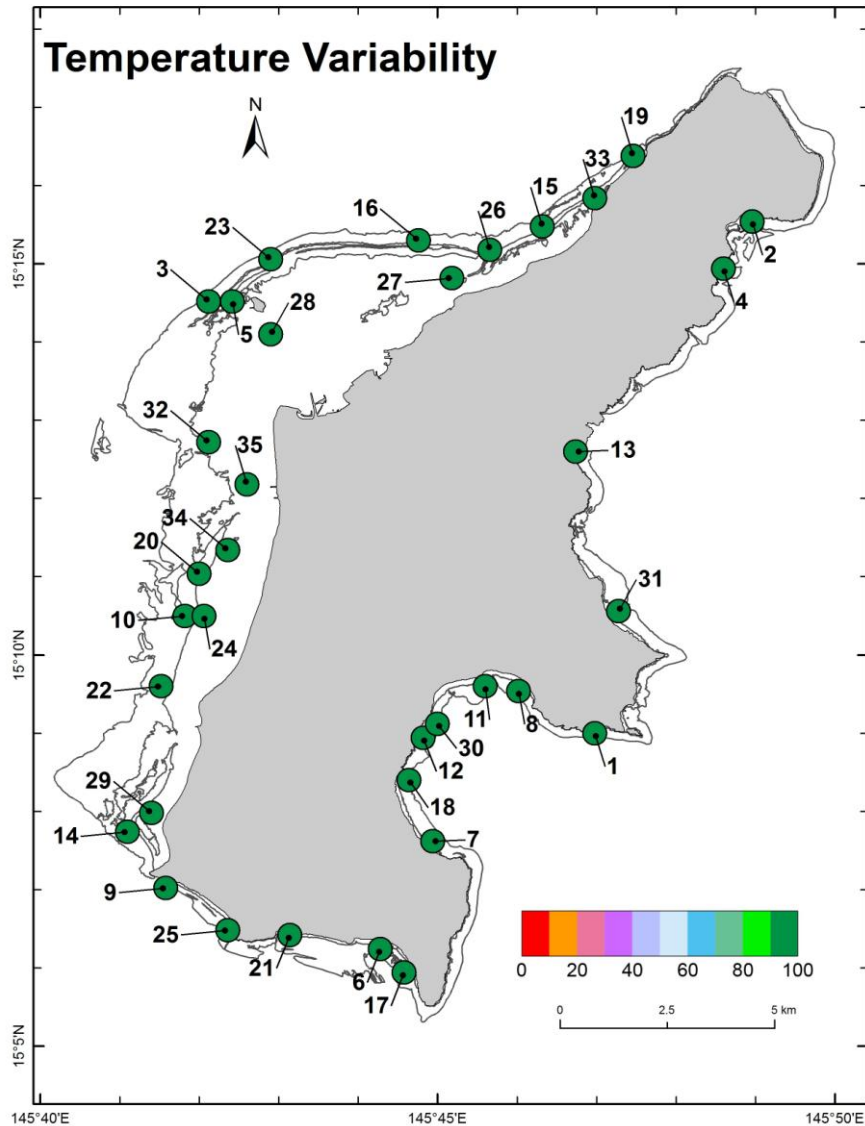

Fig. 6. Anchored scores for summer temperature variability for all survey sites.

### 3.1.5 Herbivore biomass:

There are four sites with herbivore biomass values that exceed  $2 \text{ kg}/100 \text{ m}^2$ : Bird Island ( $3.33 \text{ kg}/100 \text{ m}^2$  [2]), Nanasu Reef ( $3.01 \text{ kg}/100 \text{ m}^2$  [4]), Obyan Beach ( $2.65 \text{ kg}/100 \text{ m}^2$  [6]), and Oleai Staghorn ( $2.06 \text{ kg}/100 \text{ m}^2$  [24]). Bird Island is a no-take marine protected area and amongst the sites with greatest wave exposure (Fig. 14) so it was not surprising to find a high (relative) herbivore biomass there. The herbivore biomass at most survey sites is far lower than that seen at Bird Island (Fig. 7). Throughout the report, sites with 'low' relative scores either for resilience or individual variables are those with  $<60\%$  of the maximum value. For herbivore biomass, 31 of the 35 survey sites have  $<60\%$  of the biomass seen at Bird Island, or 'low' relative biomass (Table 2, Fig. 15). There are 11 sites with less than  $0.50 \text{ kg}/100 \text{ m}^2$  ( $<15\%$  of that seen at Bird

Island); the lowest of these is Pak Pak Beach (0.13 kg/100 m<sup>2</sup> [29]). Herbivore biomass is not correlated to fishing access ( $p=0.39$ ,  $t_{33}=0.258$  at  $r=0.04$ ).

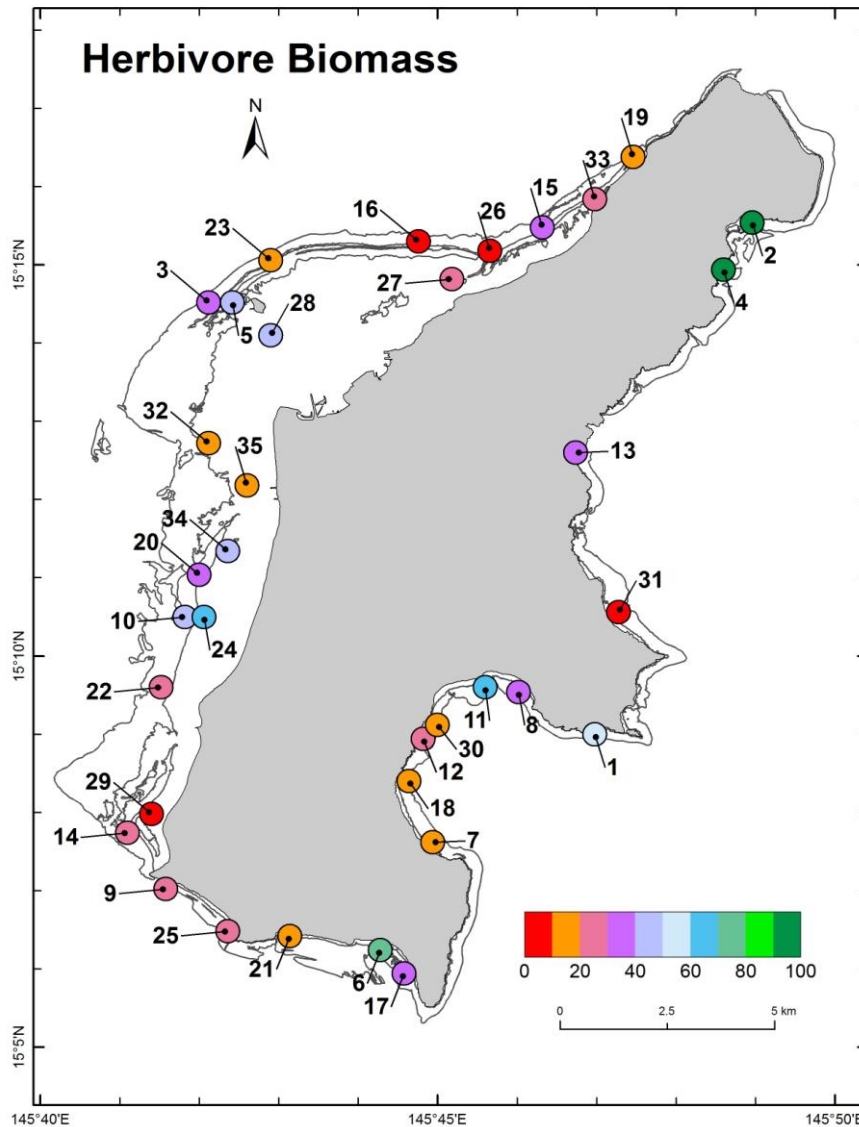

Fig. 7. Anchored scores for herbivore biomass at all survey sites.

### 3.1.5.1 Herbivorous Fish Communities

When all sites are pooled nearly half of the herbivorous fish biomass is made up of grazers/detritivores (i.e., fish that do both, Fig. 8). The remaining half is made up in near equal parts detritivore (i.e., exclusive detritivores) and scrapers/small excavators (both ~20%), and ~10% browsers, with less than 3% planktivores. For the common herbivorous fish families, Scaridae and Acanthuridae, Scarids observed were slightly larger on average than Acanthurids (Figs. 9 & 10). More than 30% of the observed Scarids were 11-15 cm, and another 30% 16-20 cm (Fig. 9). In contrast, >50% of the

Acanthurids were 11-15 cm, and less than 15% were 16-20 cm. No Acanthurids were observed larger than 30 cm (Fig. 10); a few Scarids were observed between 31 and 35 cm, and between 36 and 40 cm (Fig. 9).

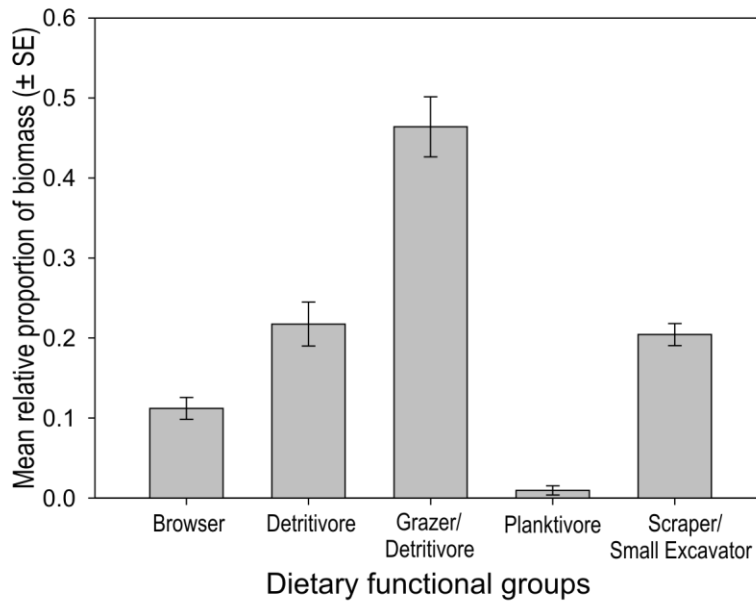

Fig. 8. Mean relative proportion across all survey sites of IUCN/NOAA designated dietary functional groups for fish species observed during the 2012 surveys. This study did not count non-herbivorous fish below 10cm in length.

Fig. 9. Size-class frequency histogram for fish within the Scaridae family observed during the 2012 surveys, pooled across all 35 survey sites.

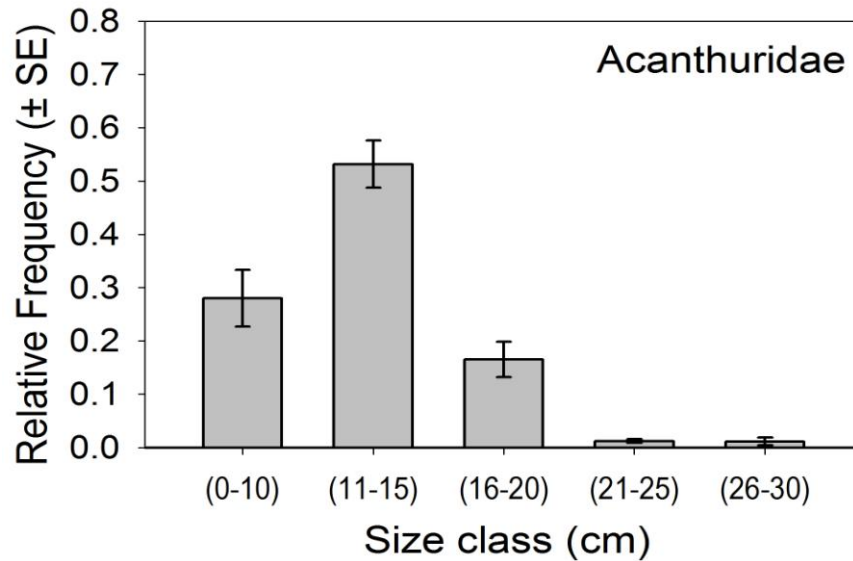

Fig. 10. Size-class frequency histogram for fish within the Acanthuridae family observed during the 2012 surveys, pooled across all 35 survey sites.

### 3.1.6 Macroalgae cover

Macroalgae was observed at less than half (16) of the 35 survey sites (see all circles *not* dark green in Fig. 11, and see Fig. 15). Only 10 of those sites have macroalgae cover that exceeds 5% of the substrate, and only five sites have macroalgae cover that exceeds 20% of the substrate. These five are: Tuturam (72.44% [30]), South Dakota (33.67% [18]), Quartermaster Staghorn (32.33% [34]), South LaoLao (24.61% [7]), and Marianas Resort (22.33% [33]). For this and the upcoming three variables (nutrient input, sedimentation and fishing access), lower values (i.e., lower macroalgae cover) are better for reef resilience. Keeping the normalized scale of 0-1 uni-directional means all values for macroalgae cover are still anchored to the maximum value (72.44% at Tuturam [30]) but then this is subtracted from 1 (see methods for more detail). Sites with less than 60% of the max value (so, once reversed, all anchored scores >0.4, Table 2), have low relative macroalgae cover. All remaining (34) sites have low relative macroalgae cover relative to Tuturam. Without exception, the highest levels of macroalgae cover (8 sites with anchored scores <0.9, sites *not* dark green in Fig. 11) are in LaoLao Bay, or in lagoon sites in western Saipan.

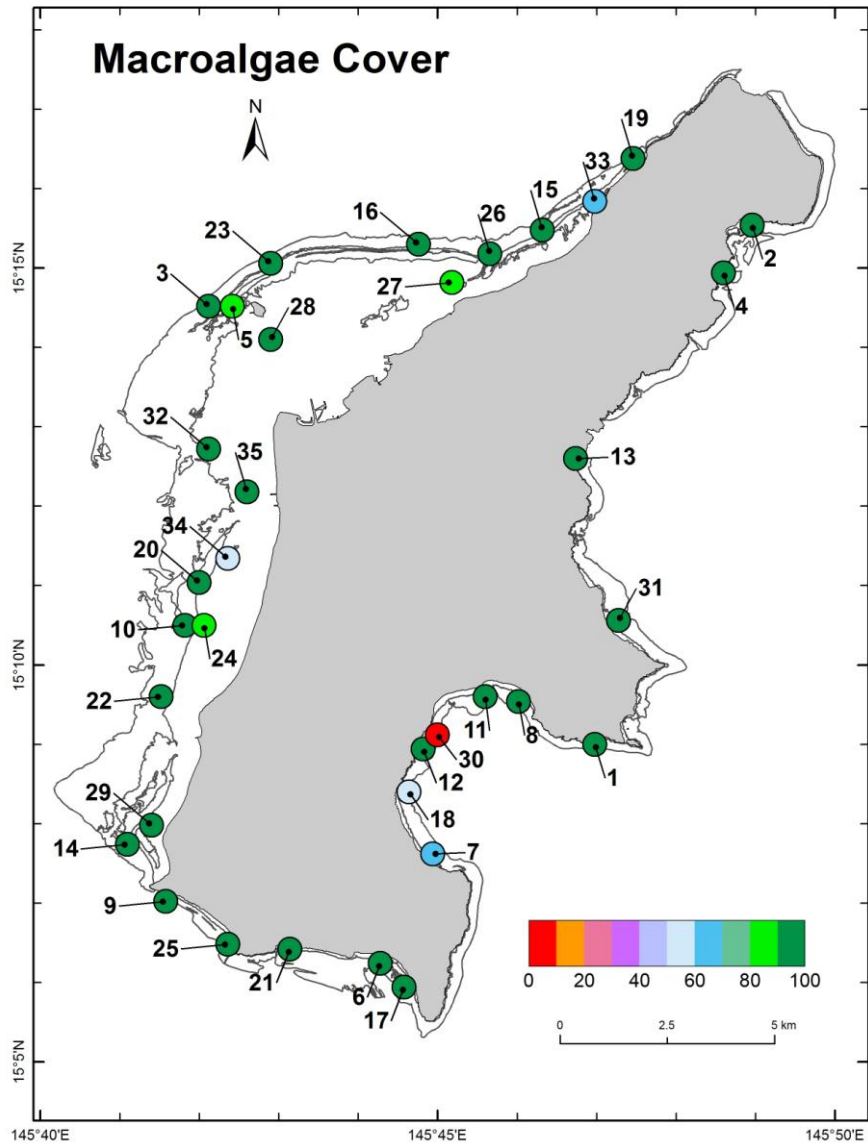

Fig. 11. Anchored scores for macroalgae cover at all survey sites. Low scores here mean high macroalgae cover.

### 3.1.7 Nutrient input & Sedimentation

Nutrient input was assumed to be directly proportional to watershed size, and sedimentation is the percentage of land made up by 'barren land/urbanized vegetation/highly developed' (see methods for more detail). The three highest nutrient input and sedimentation levels are at Tank Beach [31], MMT – Managaha Patch [28], and Peysonnelia Reef [32] (Figs. 12 & 13). Relative to the maximum levels seen, the great majority of sites have low nutrient input and sedimentation (32 of 35 sites, Table 1). The highest levels seen are at the sites geographically closest to Garapan in west Saipan, and to the large watershed adjacent to Tank Beach in the east.

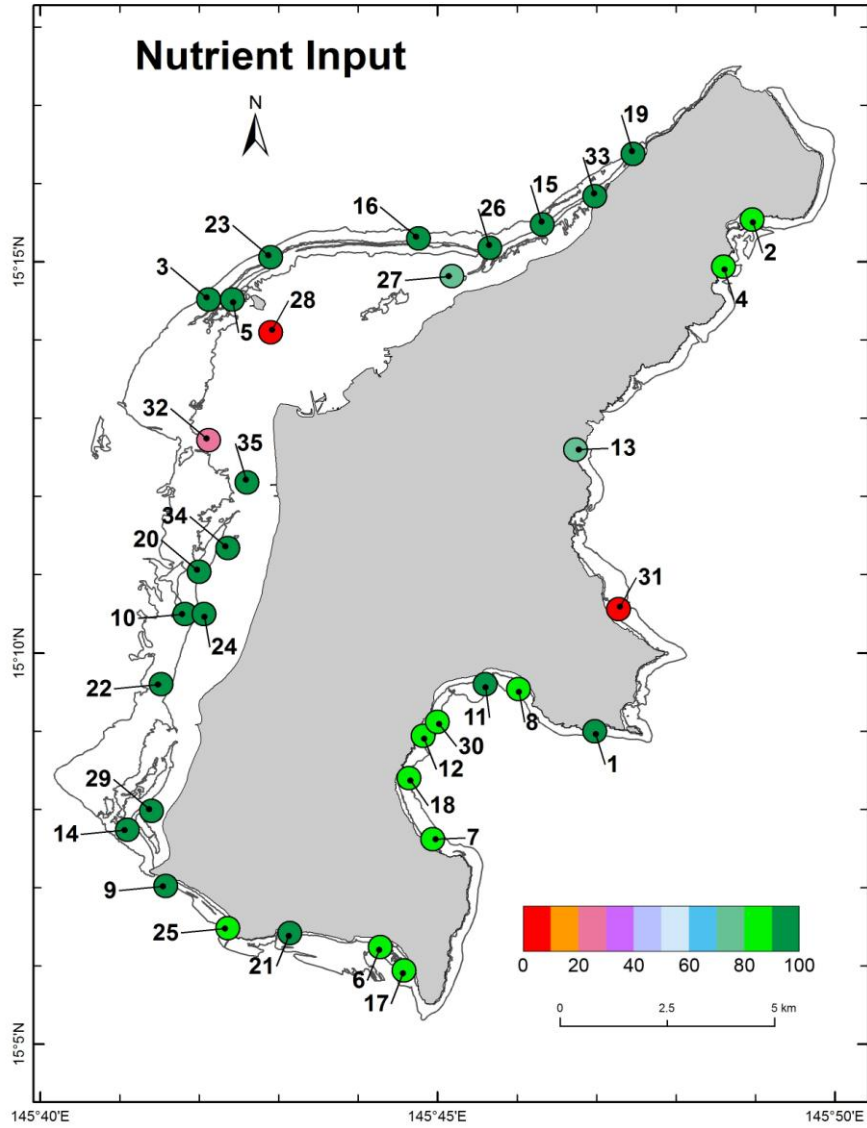

Fig. 12. Anchored scores for nutrient input at all survey sites. Low scores here mean high nutrient input.

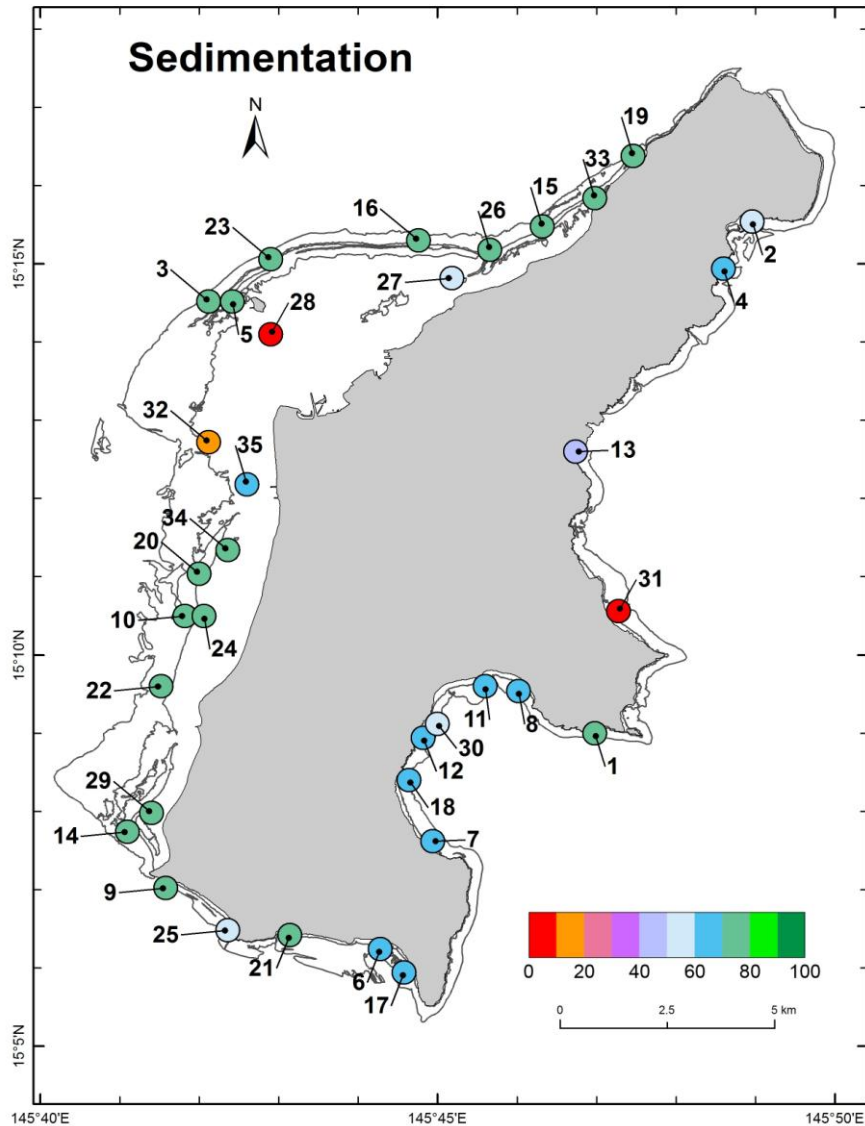

Fig. 13. Anchored scores for sedimentation at all survey sites. Low scores here mean high sedimentation.

### 3.1.8 Fishing access

There are strong spatial patterns in access to the fishery based on wave exposure and energy (Fig. 14). All sites that are not protected areas that have low fishing access (high wave exposure) are in the north east or in the exposed (central to southern) portions of LaoLao Bay; the four protected areas are all considered here to have low fishing access (Forbidden Island [1], Bird Island [2], Lanyas [3] and MMT Managaha MPA [5]). There are six sites with wave energies determined to be higher than 1000: Tank Beach [31], South LaoLao [7], Forbidden Island [1], Nanasu Reef [4], South Dakota [18], and Old Man By the Sea [13] (Table 1). There are 26 sites with wave energies lower than 500 (Table 1, Fig. 15). Overall, this results in 9 sites with low

fishing access (high wave energy >80% of max observed at Tank Beach), 1 site with medium access, and 25 with high fishing access (low wave energy >60% of max observed) (Table 1, Fig. 15). All but two of the sites with high fishing access, both of which are in northern LaoLao, are in southern or western Saipan (Fig. 14).

Fishing access had one of the greatest ranges of all of the variables examined in this report. This range created a distinction between sites that was not achieved within most of the other metrics and allowed fishing access to stand out as an important driver in the overall resilience scoring. Three decisions were made during the development of this data that should be kept in mind:

1. No-take sites were set to the best possible score (lowest level of access)
2. The correlation achieved between the manager's survey scores and wave exposure scores was the best, so we did not include distance from shore or populations center within the final metric
3. It was assumed that sites with limited fishing access would also experience less fishing pressure

Improvements to the data collected for this metric or changes regarding the decisions and assumptions above could have a significant influence on the relative importance of the fishing pressure metric. Once real fishing effort data is available this metric should be run again to establish new relative resilience scores and evaluate the accuracy of the fishing access proxy.

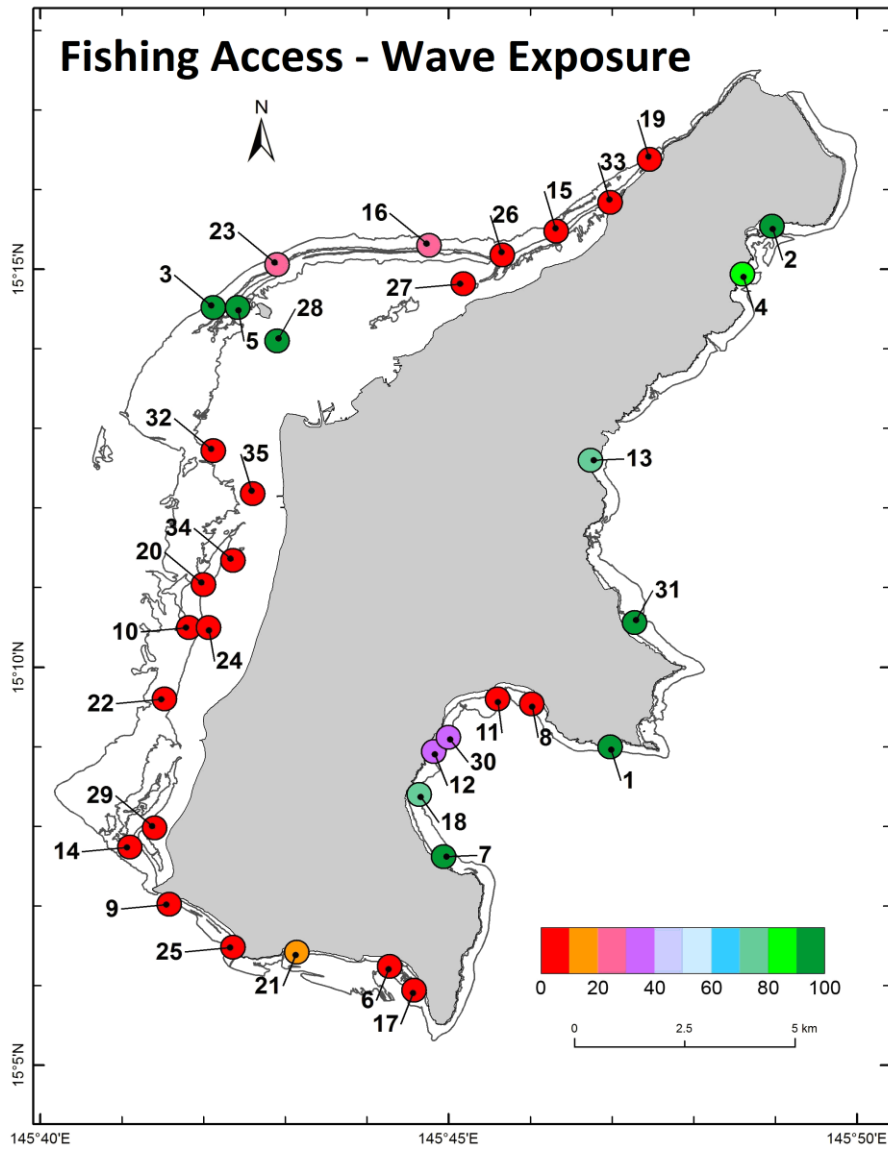

Fig. 14. Fishing access based on wave exposure at all survey sites. Low scores here mean high fishing access due to low wave exposure/energy.

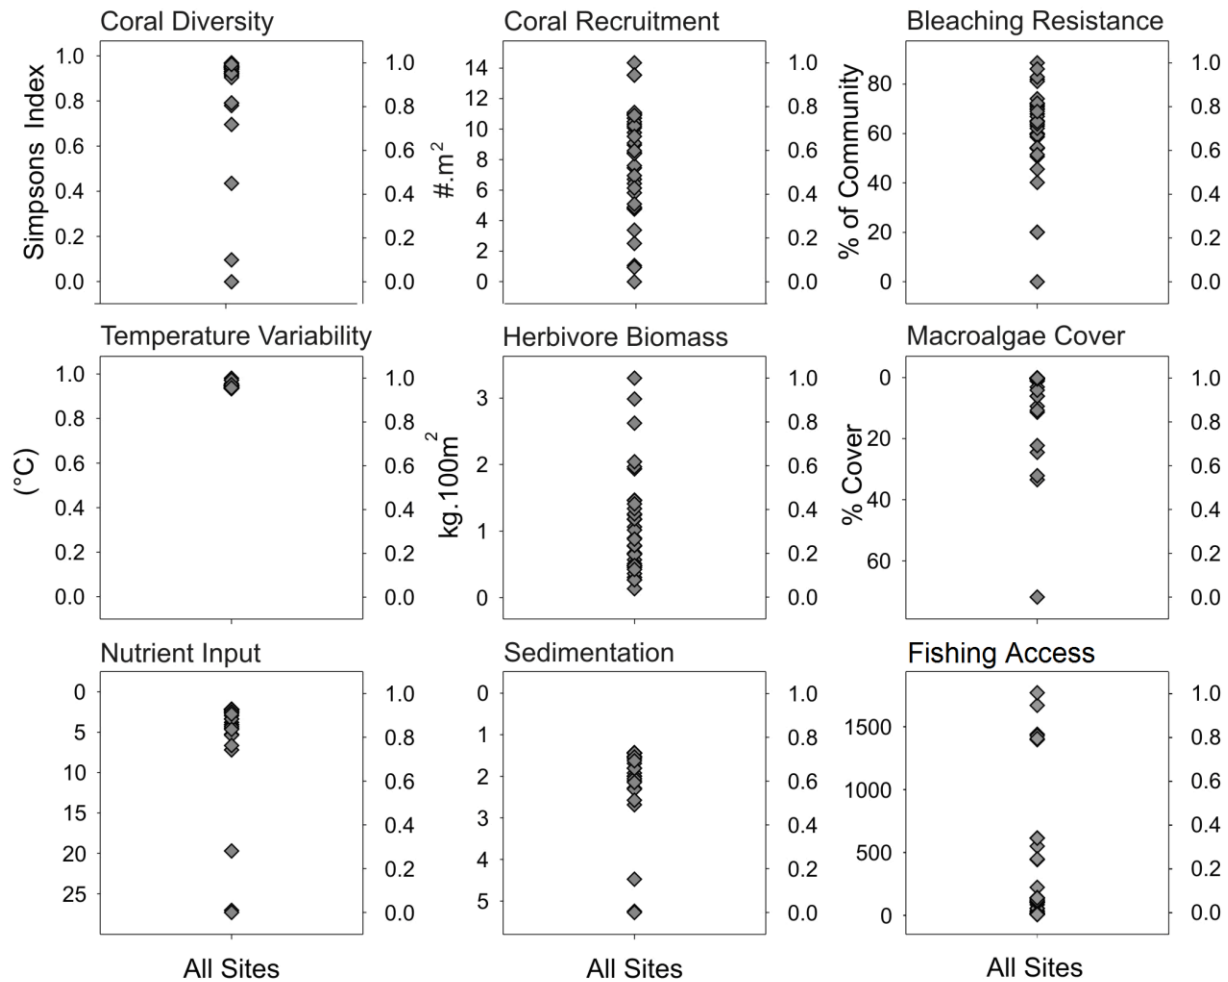

Fig. 15. Raw data values for all variables for all sites. Nutrient input, sedimentation and fishing access are all unit-less values. The values for each of the 9 variables included in the resilience analysis are also presented within Table 1 of each of the 35 site summaries that form Appendix 5.

### 3.2 Resilience Analysis

Raw data values for all variables are shown in Table 1 and referred to throughout sections within 3.1. The anchored (to the max value) and normalized (0-1 scale) scores are shown in Table 2. The resilience scores are the average of the anchored and normalized scores for all 9 variables and ranged from 0.84 (Forbidden Island) to 0.45 (Fishing Base Staghorn) (Table 2). High resilience scores were found for 23 sites (~65% of sites ranged between 0.8 and 1.0, based upon anchored resilience scores), 9 sites have medium resilience scores (26% of sites ranged between 0.6 and 0.79), and 3 sites have low resilience scores (9% of sites scored <0.59) (Table 1). Spatial patterns in the anchored resilience scores show that outer-reef sites in the west are not very different from one another in terms of resilience potential but are very different from

lagoon sites (Fig. 16). Anchored scores vary somewhat within LaoLao Bay with the central portion of the Bay having a lower resilience score than the rest of the Bay (around Tuturam [30]). Spatial patterns are easier to discern in Fig. 17, which shows high, medium, and low resilience scores in green, yellow and red, respectively. All outer reef sites in the south and west have high (relative) resilience potential (Fig. 17). Lagoon sites in the west have medium or low resilience potential. Sites in the east are a mix of high and medium; high in the northeast where reef development is limited and medium there near Tank Beach, and high throughout LaoLao Bay excepting around Tuturam [30] (Fig. 17).

Principle components analysis (PCA) indicated that high and medium resilience sites were distinguished from low resilience sites by having higher coral diversity, recruitment, and bleaching resistance (Figure 17). Conversely, low resilience sites were characterized by high fishing access, nutrient input and sedimentation, and low coral diversity (Figure 17). This can be seen in the spatial patterns in resilience potential around Saipan (Figs. 16 & 17). Most outer reef sites have similar resilience scores and the low resilience sites are all in the lagoon where fishing access is greatest and coral diversity lowest (see sites numbered 33, 34 and 35; Figs. 17 & 17). The PCA results do not suggest that coral diversity is a more important driver of resilience potential in Saipan than fishing access (as an example). Rather the PCA results show that variability is greater for some indicators than for others (Fig. 18). Since all indicators are weighted equally in the analysis here, the indicators with the greatest variability (in anchored scores) have a greater influence on the differences in resilience scores seen. Variability, as measured by the standard deviation, is lowest for temperature variability (stdev=0.01). Standard deviation values for all other variables excepting fishing access are between 0.19 (Sedimentation) and 0.25 (Recruitment); Fishing access has a standard deviation of 0.40. In this analysis, fishing access is driving differences in the final resilience scores to a greater extent than the other variables.

More details on the resilience analysis results for each site can be found in the site summaries that form Appendix 5.

Table 1. Raw data values for all 9 variables used in the resilience analysis. Survey sites are presented in ascending order by resilience ranking (see Table 2). Asterisks denote variables that are reversed in the resilience analysis such that high values for those variables mean low scores once anchored/normalized to the 0-1 scale (see Table 2, and methods for more detail).

Site Names	Rank	Resilience Score:								
		Coral Diversity	Recruitment	Bleaching Resistance	Temperature variability	Herbivore biomass	Macroalgae cover*	Nutrient input*	Sedimentation*	Fishing access

Table 2. Final resilience scores and rankings for the survey sites. Anchored (to the max value) and normalized (uni-directional 0-1 scale) scores for all 9 variables are shown to the right. Resilience scores are the average scores for all variables, then anchored to the highest resilience score (column right of rank). High relative resilience potential includes the range (0.8-1.0), medium (0.6-0.79), and low (<0.6).

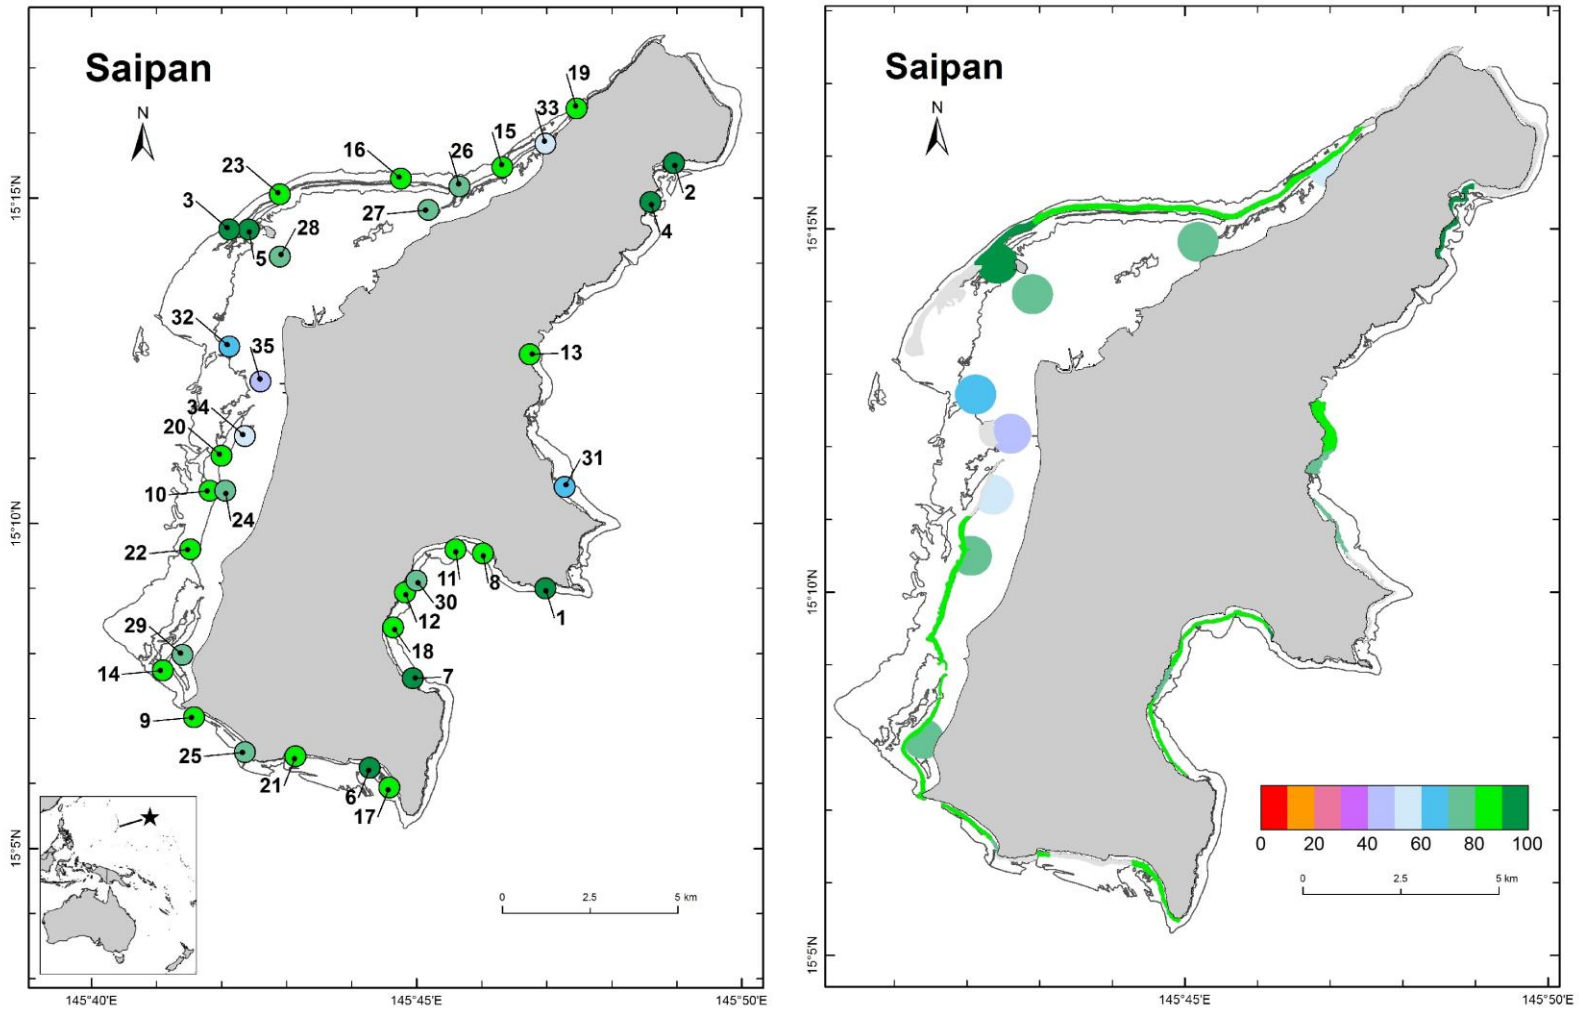

Fig. 16. Anchored resilience scores for all survey sites are shown by site on the left, and following spatial interpolation via kriging in ArcGIS on the right. Lagoonal sites are assumed to have a circular habitat area  $\sim 500 \text{ m}^2$  in diameter.

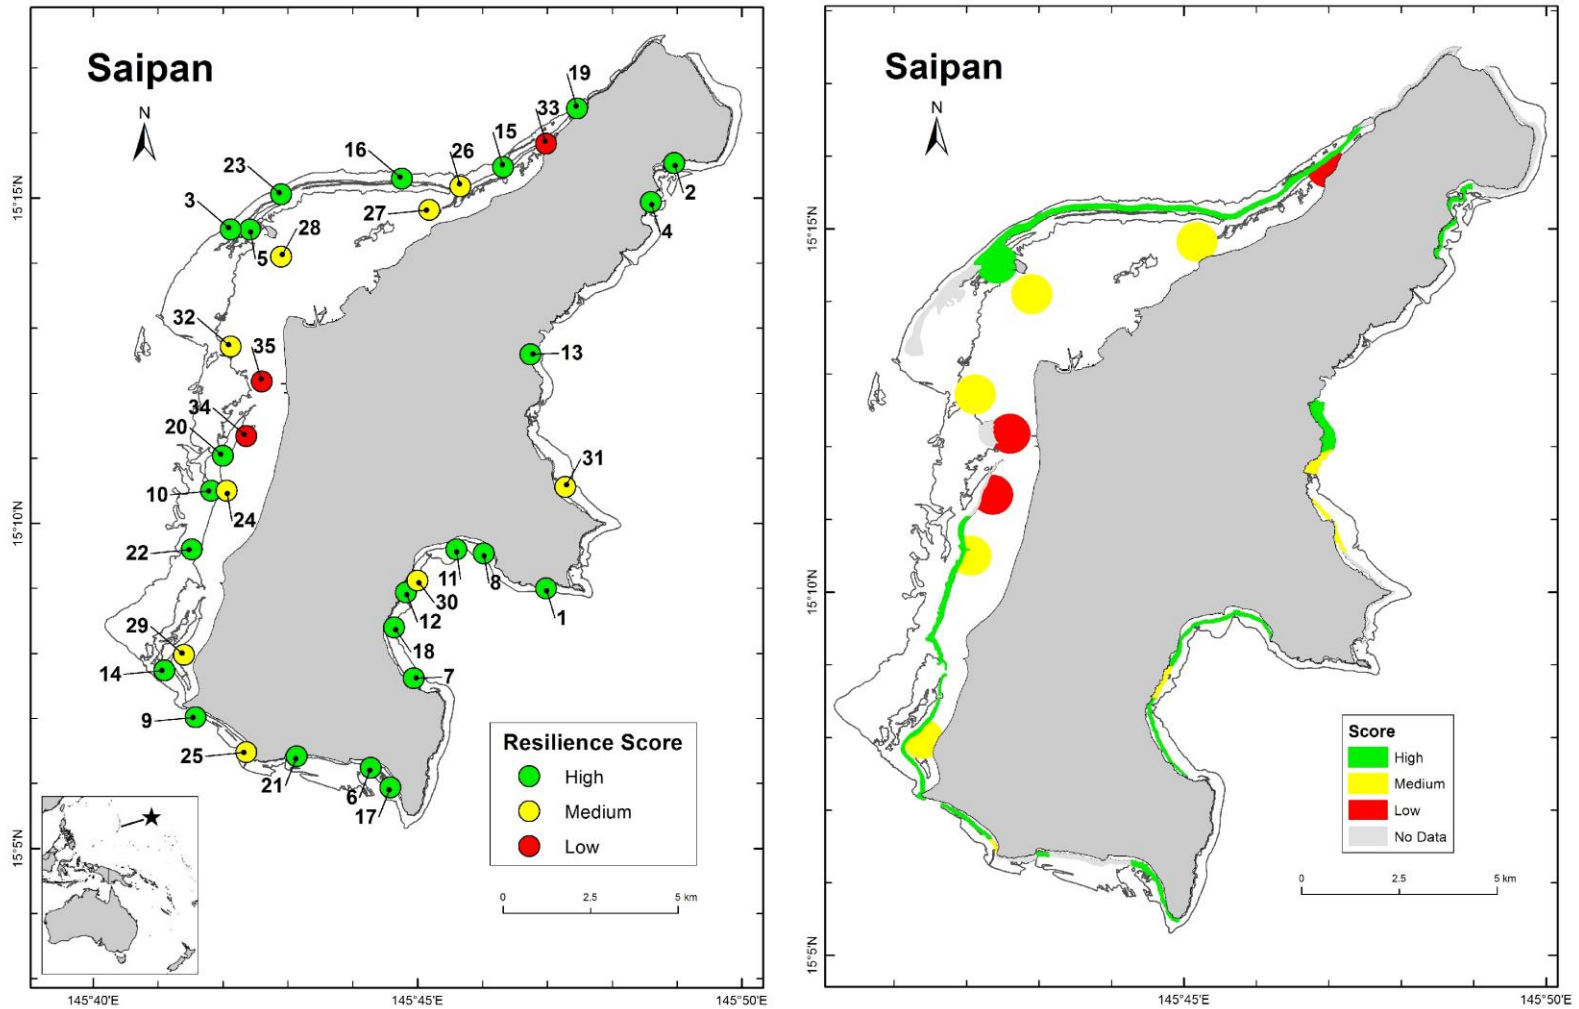

Fig. 17. High, medium and low resilience scores are shown by site on the left and refer to anchored scores between 0.8 and 1, 0.6-0.79, and  $>0.6$ , respectively. Spatial interpolation via kriging in ArcGIS is shown on the right. Lagoonal sites are assumed to have a circular habitat area  $\sim 500 \text{ m}^2$  in diameter.

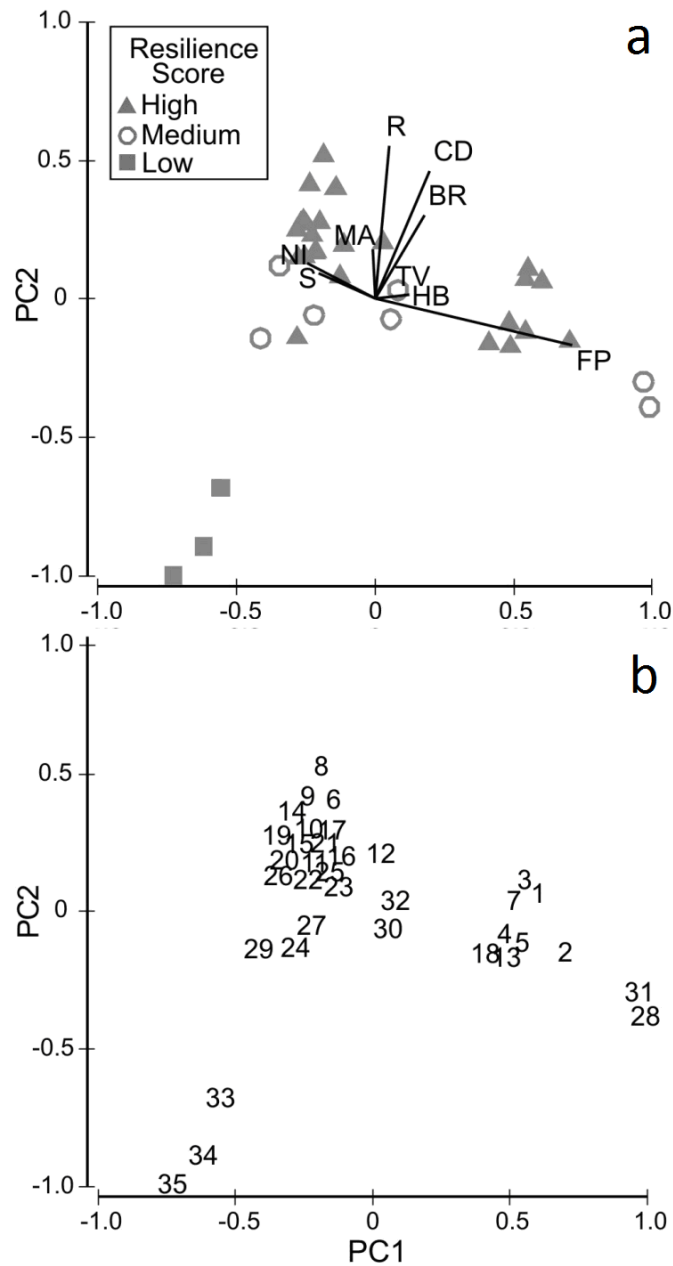

Figure 18. Both PC1 (38.7% of variation) and PC2 (22.5% of variation) were informative in understanding differences between sites. Fishing pressure (0.853) was the main driver of PC1; high fishing pressure characterized low resilience sites but there was a gradient of medium and high resilience sites along the axes in demonstrating that a range of fishing pressures scores characterized those sites. Low resilience sites were also characterized by high nutrient input (-0.296) and high sedimentation (-0.245). On the PC2 axis, high scores in coral diversity (0.556), coral recruitment (0.662), and bleaching resistance (0.211) distinguish the medium and high resilience sites from the low resilience sites.

### 3.3 Combined Anthropogenic Stress

Anthropogenic stress scores were produced by averaging anchored scores for nutrient input (section 3.1.7), sedimentation (section 3.1.7) and fishing access (section 3.1.8). Then anchoring these scores allowed us to describe anthropogenic stress at each site relative to the site assessed as having the lowest anthropogenic stress of all of the surveyed sites (Fig. 19). This process yielded 7 sites with low anthropogenic stress (1.0-0.8), 20 with medium (0.79-0.6), and 8 with high (<0.6); these are shown as green, yellow and red respectively in Table 3 and Figure 12. High levels of combined anthropogenic stress (nutrient input, sedimentation and fishing access; red in Table 3 and Figure 18) are found at locations exposed to run-off that are easy to access due to low wave exposure (Fig. 19). There are 8 of these locations: Obyan Beach [6], LaoLao Bay East [8], Boy Scout [17], Coral Ocean Point [25], Tanapag Staghorn [27], Managaha Patch Reef [28], Tank Beach [31], and Peysonnelia Reef [32]. Three of these sites – Obyan Beach [6], LaoLao Bay East [8] and Boy Scout [17] – have high resilience so can be considered priorities for local-scale actions to reduce one or all of the three anthropogenic stressors (see also section 4).

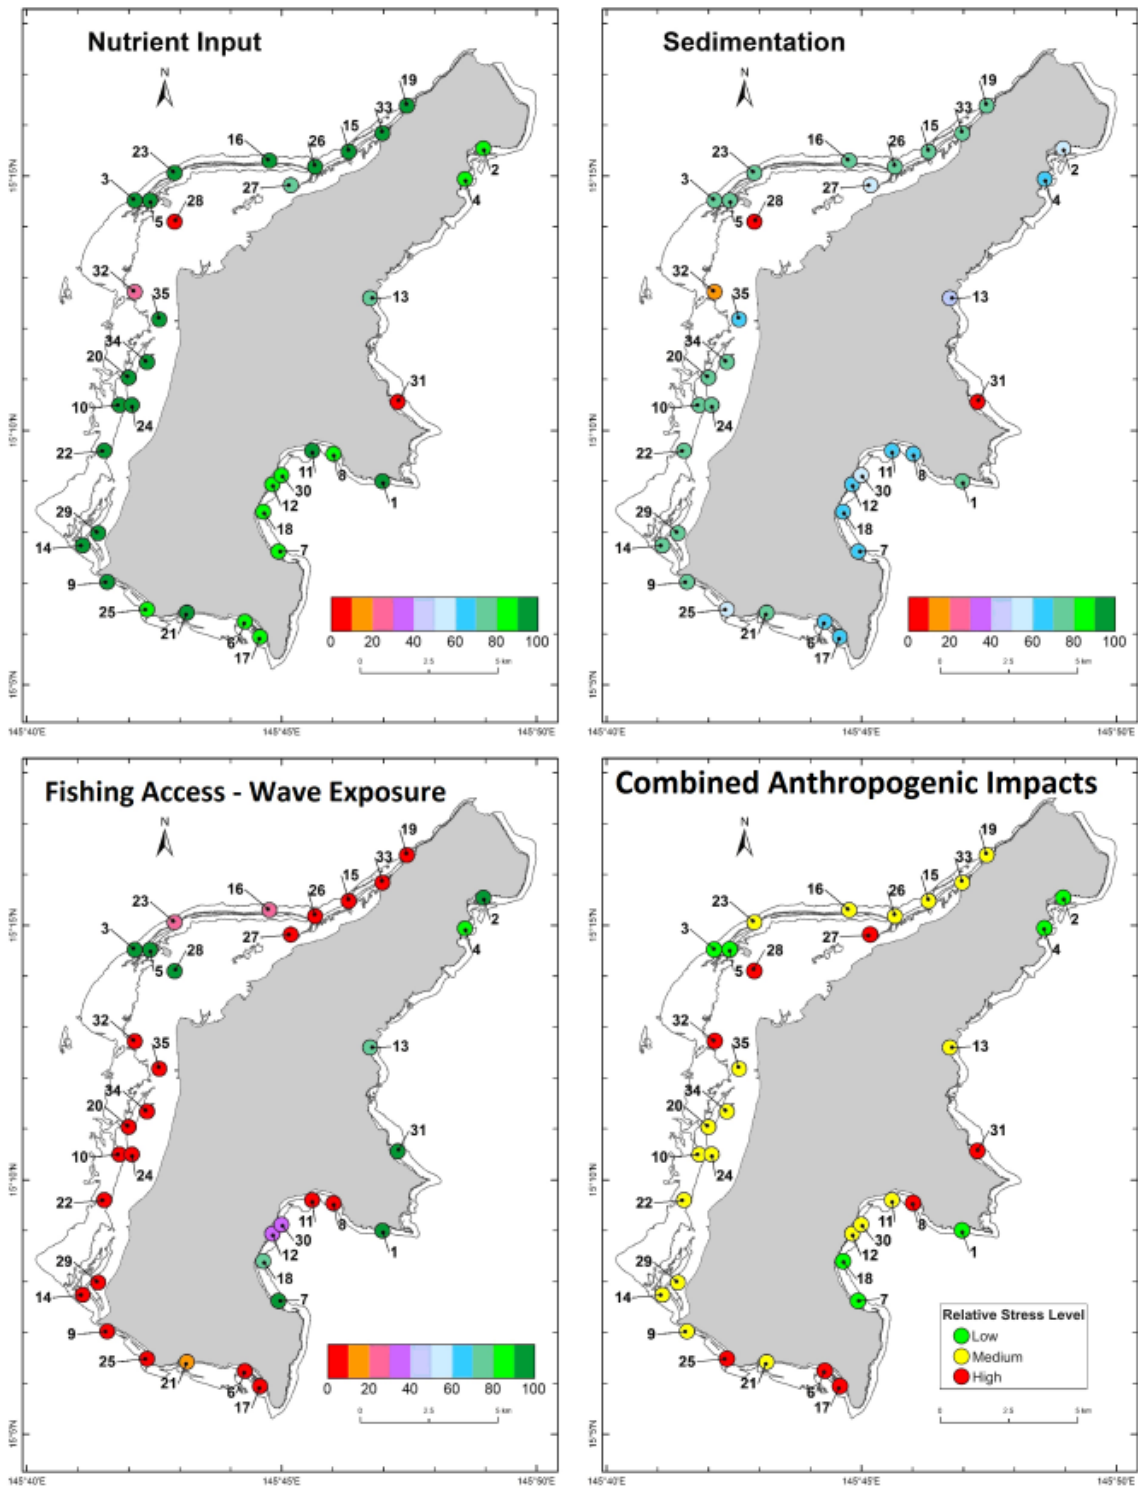

Figure 19. Anchored scores for nutrient input (see also Fig. 12), sedimentation (see also Fig. 13), and fishing access (see also Fig. 14), and all anthropogenic stressors combined. High, medium and low relative stress in the bottom right refers to <0.6, 0.6-0.79, and 0.8-1.0, respectively, in the anchored scores column of Table 3. Table 3. Combined anthropogenic stress scores for all sites; the average of the anchored scores for nutrient input, sedimentation and fishing access (also shown in

Table 3. High, medium and low relative stress in the colored column is based on <0.6, 0.6-0.79, and 0.8-1.0, respectively, in the anchored score column.

Site Names	Resilience rank	Anchored score	Average score	LMH	Nutrient input	Sedimentation	Fishing access
Forbidden Island	1	0.98	0.87	L	0.91	0.70	1.00
Bird Island	2	0.90	0.79	L	0.81	0.57	1.00

MMT - Outside Grand Hotel	22	0.65	0.57	M	0.93	0.73	0.06
Elbow Reef	23	0.72	0.64	M	0.93	0.73	0.25
Oleai Staghorn	24	0.62	0.55	M	0.93	0.73	0.00
Coral Ocean Point	25	0.54	0.48	H	0.81	0.56	0.06
Achugao	26	0.65	0.57	M	0.93	0.73	0.06
Tanapag Staghorn	27	0.48	0.43	H	0.76	0.51	0.00
MMT - Managaha Patch Reef	28	0.38	0.34	H	0.01	0.00	1.00
Pak Pak Beach	29	0.63	0.55	M	0.93	0.73	0.01
Tuturam	30	0.67	0.59	M	0.84	0.59	0.35
Tank Beach	31	0.38	0.33	H	0.00	0.00	1.00
Peysonnelia Reef	32	0.19	0.17	H	0.28	0.15	0.08
Marianas Resort	33	0.61	0.54	M	0.92	0.71	0.00
Quartermaster Staghorn	34	0.63	0.55	M	0.93	0.73	0.01
Fishing Base Staghorn	35	0.60	0.54	M	0.91	0.69	0.01

For locations highly susceptible to bleaching, factors such as herbivore biomass and fishing access are particularly important. Herbivory is important at locations with high susceptibility to bleaching (relative to other sites in the area) because herbivores can reduce the cover of macroalgae; a major competitor of corals for space on reefs (review in Hughes et al. 2007). Healthy herbivore populations can help facilitate the recovery of coral populations following bleaching or other disturbance events that cause coral mortality (McCook 1999).

Seven locations (20% of those surveyed) are highly susceptible to bleaching (i.e., sites where the bleaching resistance (anchored) score is less than 0.60; Table 4). Bleaching resistance here is the percentage of the community made up by coral species that are generally resistant to bleaching. These bleaching susceptible locations will recover more slowly if processes like herbivory are not intact. Herbivore biomass is less than 50% of that seen at the site with the max herbivore biomass (anchored scores <0.5, Table 2). Further, fishing access based on wave exposure is high at all seven of these locations. These locations are likely to be amongst the most vulnerable surveyed given their sensitivity to bleaching and their accessibility to fishers, which may lengthen recovery timeframes between disturbance events. These sites warrant special attention during management and conservation planning.

Table 4. Vulnerable sites with low scores for bleaching resistance, low herbivore biomass and high fishing access based on wave exposure.

Rank	Site name	Bleaching resistance	Herbivore biomass	Fishing Access
35	Fishing Base Staghorn	0	0.13	0.01
33	Marianas Resort	0.23	0.26	0
34	Quartermaster Staghorn	0.23	0.42	0.01
26	Achugao	0.45	0.08	0.06
29	Pak Pak Beach	0.51	0.04	0.01
19	Wing Beach	0.57	0.17	0.08
25	Coral Ocean Point	0.58	0.2	0.06

The benthic community composition at the time of surveys can be found for all sites in Appendix 3. Appendix 4 contains the full list of coral species seen at the survey sites that were listed as potentially endangered on a petition in 2009 and given proposed classifications by NMFS in December of 2012.

#### 4. Suggestions for managers

Based on the resilience analysis above, our team has made a number of suggestions to coral reef and coastal managers working in CNMI. These suggestions, detailed below, are based on the following approaches and rationale:

1. Climate change projections suggest that reef condition will decline through this century as disturbance frequencies increase. Managers should invest some resources in protecting high resilience sites if it can take many years or even decades for the benefits to manifest (as reported in McClanahan et al. 2013). This is because maximizing the number of healthy reefs in the long-term requires protecting the 'strong', or 'higher resilience potential' sites, if you expect most reefs to be in a degraded state (as we do, in the longer-term; Game et al. 2008). In our analysis, scores for resilience potential are partially driven by anthropogenic stressors. This creates the possibility that sites in the analysis could only differ in levels of anthropogenic stress but otherwise have the same resilience potential. We do not separate resilience indicators relating to anthropogenic stress from the other indicators. This is because we cannot defensibly quantify what the legacy of past anthropogenic stress will be. For management actions that result in benefits that take many years or decades to manifest – like marine protected areas – we suggest that sites shown here as having higher relative resilience potential deserve greater consideration. Further, we suggest reducing anthropogenic stress to the extent possible at the sites assessed as having the highest resilience potential.
2. Sites with greater coral diversity and low macroalgae cover deserve special consideration from managers as these may be high tourism value sites.
3. Actions resulting in improved water quality on reefs will affect the resilience potential of the greatest number of sites (versus other actions).
4. Protecting herbivorous fish populations is especially important at locations with greater relative vulnerability to coral bleaching.
5. Anchoring to the local maxima means this analysis of relative resilience potential for Saipan would change if sites were included from more remote locations in CNMI. This feature of the analysis highlights the importance of continuing and advancing the research and work presented here.

The suggestions for managers include:

- Obyan Beach, LaoLao Bay East, Agingan Point, and Oleai rocks are the four sites with resilience scores in the top ten that are currently not part of a marine protected area, and have high fishing access based on wave exposure. These are strong candidates for fishing pressure studies, focused enforcement presence or area based management since they have high resilience potential and are not protected from fishing by wave exposure. Further, coral diversity is extremely high at these locations. Another benefit of protecting these sites is that they are also likely to create positive growth opportunities for local dive and snorkel-based tourism operations.
- There are three sites with high resilience scores that have high anthropogenic stress: Obyan Beach, LaoLao Bay East, and Boy Scout. These warrant special consideration from managers as they represent priorities for targeted actions to reduce anthropogenic stress, specifically reducing nutrient input, sedimentation, and implementing studies to better understand the relationship between fishing

access, fishing pressure and what is actually being harvested from these locations.

- There are five sites with high resilience potential, higher than average coral cover (>38%), and medium combined anthropogenic stress scores: Agingan Point [8], Point Break Reef [14], Wing Beach [19], Lighthouse Reef [20], and Elbow Reef [23]. These sites could warrant special attention to managers given their high relative resilience potential and that they might be of great present or future importance to dive and tour operators.
- The most resilient sites typically had low fishing access based on wave exposure, high herbivore biomass and low macroalgae cover. Suites of actions that address these issues on a broader scale, like the existing gillnet and scuba-spear ban, help to increase resilience potential at many sites around Saipan and need to be an ongoing management consideration as does the successful enforcement of these regulations.
- All of the sites assessed as having low or medium resilience have very low scores for one or more of: nutrient input, sedimentation, and fishing access. Scores for all of the other variables vary less among the pool of sites than these three anthropogenic stressors. Whole-of-island and local-scale targeted actions to reduce these stressors will maximize the number of healthy reef sites around Saipan as the frequency of climate-related disturbances increases.
- The three sites with low relative resilience – Marianas Resort, Quartermaster Staghorn, and Fishing Base Staghorn – are all highly vulnerable to temperature-induced bleaching. This is also true for Achugao, Pak Pak Beach, Wing Beach, and Coral Ocean Point. At all seven of these locations, bleaching resistance is low (<0.6), herbivore biomass is less than half of that seen at the site with the max biomass, and fishing access is high. These are vulnerable locations that warrant special consideration from managers. Three of these – Marianas Resort, Quartermaster Staghorn and Fishing Base Staghorn - are also critical lagoonal nursery habitats for fish. These areas could be a focus of community monitoring programs, like CoralWatch, given their vulnerability and accessibility. People participating in the monitoring can help keep trash off these reefs, and provide early warnings of bleaching impacts at these sites if bleaching is observed.
- The analysis approach of anchoring scores to local maxima means the analysis results are sensitive to the pool of sites included in the analysis; including more sites may raise the maxima, meaning sites with current high relative scores may have medium or low relative scores and vice versa. This is critically important in CNMI where most of the territory's population resides on one island, Saipan. Surveying the reefs around the lesser populated islands, like Tinian and Rota, is an important next step. To that end, 2013-2014 funding was recently secured through the NOAA Internal call to fund a continuation of this work on Tinian.

These additional surveys have the potential to reveal the extent to which habitat condition and reef resiliency differ between Saipan and other locations with lower anthropogenic stress (see next steps section below).

## **5. Next steps**

The lead investigator, J. Maynard, will continue to work closely with managers from CNMI's Division of Environmental Quality and the local NOAA fisheries field office for at least 18 months from this report's submission date. The team will work together to provide guidance for local managers based on the implications of the findings from the resilience analysis. Over the next several months, the project team will share project results in relevant conservation meetings. The project team is also preparing a manuscript on the resilience analysis for a conservation journal. This manuscript will address a critical science gap for conservation managers by providing much needed case studies of the development and implementation of coral reef resilience assessments.

In mid-2013 (May and June), the project team is planning further fieldwork in CNMI. A research proposal was submitted to NOAA's Coral Reef Conservation Program in September of 2012 to increase the geographic extent of the fieldwork and resilience analysis described here. This proposal was successful and the new project funds will cover surveying 30-40 sites around the islands of either Tinian or Rota (FY13). The same field and desktop methodologies will be applied as presented in this report, and the approach will be updated to include recommendations, observations and advances in our understanding of how to best analyze the data. Following the fieldwork, the project team will be able to re-assess the maxima for each variable used to anchor scores in the present analysis. This will increase our understanding of the effects of anthropogenic stressors on relative resilience potential in CNMI since anthropogenic stress is far lower on the reefs surrounding Rota and Tinian than Saipan. For example, a site currently thought to have high herbivore biomass (when the Saipan biomass maxima is used) may have low biomass relative to that found on reefs around Tinian and/or Rota. Expected outcomes of the proposed 2014 fieldwork and analysis include: 1) a revised analysis of the relative resilience potential of sites throughout CNMI that is inclusive of sites near populated and unpopulated areas; 2) a report containing management recommendations to all local government agencies regarding actions to reduce stress on reefs and support recovery processes; 3) a publication on resilience analysis methodologies focusing on ways to maximize distinguishing sites at the local-scale while also being able to compare results between geographically disparate areas; and 4) user-friendly tools for practitioners based on (3).

## Appendices

### Appendix 1 – Survey Site Waypoints

The latitude and longitude coordinates for all survey sites are shown below in decimal degrees, sorted in ascending order by resilience ranking.

Resilience rank	Site name	Latitude (N)	Longitude (E)
1	Forbidden Island	15.15	145.783
2	Bird Island	15.259	145.816
3	Lanyas	15.242	145.702
4	Nanasu Reef	15.249	145.81
5	MMT - Managaha MPA	15.242	145.707
6	Obyan Beach	15.104	145.738
7	South Laolao	15.127	145.749
8	Laolao Bay East	15.159	145.767
9	Agingan Point	15.117	145.693
10	Oleai Rocks	15.175	145.697
11	Laolao Bay Mids	15.16	145.76
12	North Dakota	15.149	145.747
13	Old Man By the Sea	15.21	145.779
14	Point Break Reef	15.129	145.685
15	Pau Pau	15.253	145.761
16	Achu Dangkulu	15.255	145.746
17	Boy Scout	15.099	145.743
18	South Dakota	15.14	145.744
19	Wing Beach	15.273	145.791
20	Lighthouse Reef	15.184	145.7
21	Ladder Beach	15.107	145.719
22	MMT - Outside Grand Hotel	15.16	145.692
23	Elbow Reef	15.251	145.715
24	Oleai Staghorn	15.175	145.701
25	Coral Ocean Point	15.108	145.706
26	Achugao	15.248	145.754
27	Tanapag Staghorn	15.247	145.753
28	MMT - Managaha Patch Reef	15.235	145.715
29	Pak Pak Beach	15.133	145.69
30	Tuturam	15.152	145.75
31	Tank Beach	15.176	145.788
32	Peysonnelia Reef	15.212	145.702
33	Marianas Resort	15.264	145.783
34	Quartermaster Staghorn	15.189	145.706
35	Fishing Base Staghorn	15.203	145.71

## Appendix 2 – Bleaching Susceptibility Ratings

The table below shows the names of all of the species observed during these surveys, between March and May of 2012. Bleaching susceptibility is rated from 1-5 with 5 being the most susceptible. These ratings come from a focus group that reviewed available literature as well as field observations from the only known bleaching event on reefs in Saipan in 2001. Coral species were considered resistant at ratings  $\leq 3$  (see methods for more detail). Habitat classifications are as follows, and refer to the types of habitat(s) the species is known to occur in CNMI: Lf = loose framework reef, P = patch reef, Rf = reef flat, SG = spur and groove reef.

Species name	Growth Form	Bleaching Susceptibility	Habitat
<i>Acanthastrea brevis</i>	Encrusting	2	P, Sg
<i>Acanthastrea echinata</i>	Encrusting	2	Lf, P, Rf, Sg
<i>Acanthastrea hillae</i>	Encrusting	2	P, Sg
<i>Acropora aspera</i>	Staghorn	5	P, Rf
<i>Acropora teres</i>	Staghorn	5	P
<i>Acropora copiosa</i>	Staghorn	5	P
<i>Acropora formosa</i>	Staghorn	5	P
<i>Acropora azurea</i>	Digitate/corymbose	4	Lf, Sg
<i>Acropora cuneata</i>	Arborescent	2	P
<i>Acropora digitifera</i>	Digitate/corymbose	3	Lf, P, Sg
<i>Acropora gemmifera</i>	Digitate/corymbose	3	Lf, Sg
<i>Acropora humilus</i>	Digitate/corymbose	3	Lf, Sg
<i>Acropora juv.</i>	Digitate/corymbose	3	Lf, P, Sg
<i>Acropora monticulosa</i>	Arborescent	3	Lf, Rf, Sg
<i>Acropora nasuta</i>	Digitate/corymbose	5	Lf, Sg
<i>Acropora palifera</i>	Arborescent	2	Lf, P, Sg
<i>Acropora secale</i>	Digitate/corymbose	3	Lf, Sg
<i>Acropora surculosa</i>	Digitate/corymbose	3	Lf, P, Sg
<i>Acropora tenuis</i>	Digitate/corymbose	5	Lf, P, Rf, Sg
<i>Acropora vaughani</i>	Digitate/corymbose	3	Lf, Rf, Sg
<i>Acropora verweyi</i>	Digitate/corymbose	4	Lf, P, Sg
<i>Astreopora listeri</i>	Massive	4	Lf, P, Sg
<i>Astreopora myriophthalma</i>	Massive	4	Lf, P, Sg
<i>Astreopora randalli</i>	Massive	4	Lf, P, Sg
<i>Cyphastrea chalcidicum</i>	Massive	3	Lf, Sg
<i>Cyphastrea japonica</i>	Massive	3	Sg
<i>Cyphastrea ocellina</i>	Massive	3	Lf, Sg
<i>Cyphastrea serailia</i>	Massive	3	Lf, Sg

<i>Cyphastrea sp. 1</i>	Massive	3	Rf
<i>Echinopora lamellosa</i>	Plate	2	Lf, P, Sg
<i>Favia favius</i>	Massive	3	Lf, P, Sg
<i>Favia matthaii</i>	Massive	3	Lf, P, Sg
<i>Favia rotumana</i>	Massive	3	P
<i>Favia speciosa</i>	Massive	3	Lf, P, Sg
<i>Favia stelligera</i>	Massive	4	Lf, Sg
<i>Favites abdita</i>	Encrusting	2	Lf, P, Sg
<i>Favites flexuosa</i>	Massive	2	Lf, P
<i>Favites russelli</i>	Encrusting	1	Lf, P, Rf, Sg
<i>Fungia scutaria</i>	Free-living	2	Lf, P, Sg
<i>Galaxea fascicularis</i>	Encrusting	3	Lf, P, Sg
<i>Goniastrea aspera</i>	Massive	4	P
<i>Goniastrea edwardsi</i>	Massive	4	Lf, P, Rf, Sg
<i>Goniastrea pectinata</i>	Massive	3	Lf, P, Sg
<i>Goniastrea retiformis</i>	Massive	4	Lf, P, Rf, Sg
<i>Goniopora fruiticosa</i>	Massive	1	Lf, Sg
<i>Goniopora minor</i>	Massive	1	P
<i>Heliopora coerulea</i>	Columnar	1	Lf, P, Rf
<i>Hydnophora microconos</i>	Massive	4	Lf, P, Rf, Sg
<i>Leptastrea bottae</i>	Encrusting	2	P, Sg
<i>Leptastrea purpurea</i>	Encrusting	2	Lf, P, Sg
<i>Leptastrea transversa</i>	Encrusting	2	Lf, Sg
<i>Leptoria phrygia</i>	Massive	3	Lf, P, Rf, Sg
<i>Leptoseris mycetoseroides</i>	Encrusting	3	P
<i>Lobophyllia corymbosa</i>	Massive	3	Lf, Sg
<i>Lobophyllia hemprichii</i>	Massive	3	Sg

---

## Appendix 3 – Benthic Community Composition

The benthic community composition varies widely among the survey sites. Coral cover ranges from 3 to 100%, bare substrate (minor turf algae if any on coral pavement) 0-81%, and macroalgae cover from 0-72% (Fig. Ap3.1 below). Benthic community composition is only included in the resilience analysis explicitly in the form of macroalgae cover, though the community make-up drives two other variables included; coral diversity and bleaching resistance. For this reason, sites with lower than average (38% across all survey sites) coral cover can and are classified as having high (relative) resilience potential in the resilience analysis (section 3.2, and Table 2, main report). Differences in the proportion of the substrate made up by common groups (i.e., live coral, macroalgae, etc.) provide an indication of habitat condition. Such information complements the resilience rankings and classifications (Table 2, main report) and the combined anthropogenic stress scores (Table 3, and Fig. 17, main report). The piechart panel that forms Fig. Ap3.1 below shows the resilience rankings and classifications (High/Medium/Low, see also Tables 1 and 2, main report), the benthic community composition, and the combined anthropogenic stress classification (from Table 3, main report). The panel graphic (Fig. Ap3.1 below) reveals that there are five sites with high resilience potential, higher than average coral cover (>38%), and medium combined anthropogenic stress scores: Agingan Point [8], Point Break Reef [14], Wing Beach [19], Lighthouse Reef [20], and Elbow Reef [23]. These sites could warrant special attention to managers given their high relative resilience potential and that they might be of great present or future importance to dive and tour operators.

More details on benthic community composition at the survey sites can be found in the site summaries that form Appendix 5.

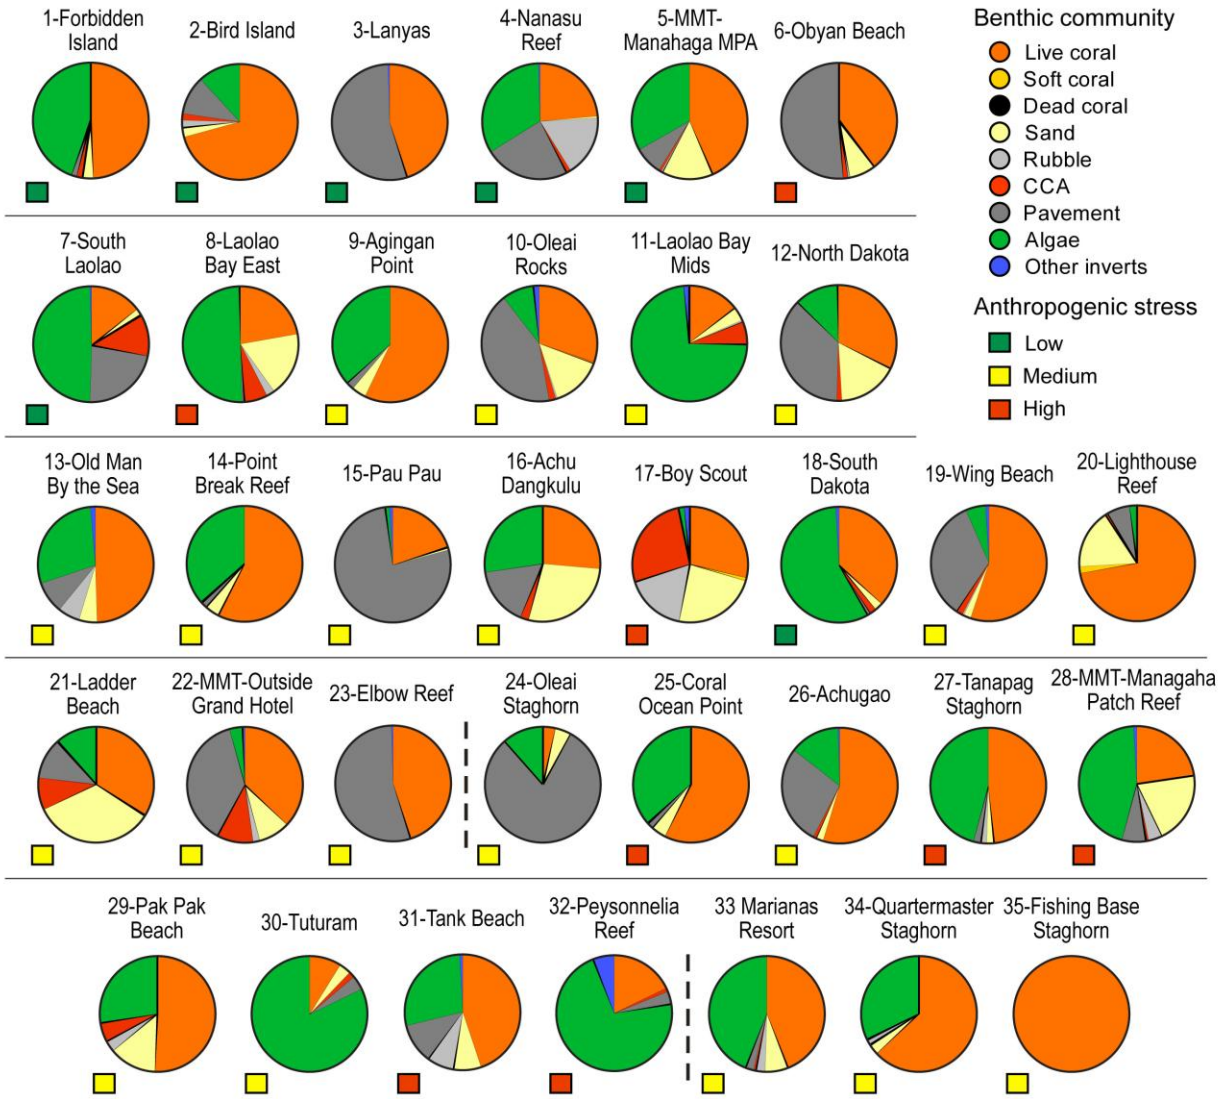

Fig. Ap3.1. The proportion of the substrate made up by 9 groups, at all survey sites. Sites are presented in ascending order based on resilience rankings (left to right); dashed lines separate high and medium (sites ranked 23/24) and medium and low (sites ranked 32 and 33) resilience sites. Boxes left and below each pie-chart denote combined anthropogenic stress as low, medium and high (see Table 3, main report).

## Appendix 4 – ESA Listings of Coral Species by the NMFS

In 2009, 82 coral species were petitioned for listing under the Endangered Species Act by the Center for Biological Diversity. 40 of those species are known to occur on reefs within the borders of CNMI. On November 30<sup>th</sup> 2012, the NMFS released their proposed ruling on the petition, which recommended 66 of the initial 82 species be listed as either threatened or endangered. Of the 40 petitioned species known to be in CNMI, 28 were proposed by NMFS to be classified as ‘threatened’, 1 as ‘endangered’ (*Millepora foveolata*), and 11 as ‘not warranted’. A total of 23 of the 40 petitioned species known to be in CNMI were observed during these surveys (March-May, 2012) or during surveys conducted by the Marine Monitoring Team in 2009 (Table 1 below). 14 of these 23 have now been proposed by NMFS as ‘threatened’ (left-side of Table 1 below, grey shade), and 9 are proposed as ‘not warranted’.

The threatened coral species seen at the greatest number of sites are *Acropora verweyi* and *Pocillopora danae*, 21 and 18 sites, respectively. At least one coral species proposed as threatened was seen at all but one of the survey sites; South LaoLao. The coral species listed in the original 2009 petition that we observed at each survey site are listed again in Table 2 within each of the 35 site summaries that form Appendix 5.

Table 1. Coral species petitioned in 2009 for listing under the Endangered Species Act. The threatened and not warranted classifications are those proposed by the NMFS in November of 2012. X's denote locations where the coral was observed during these or surveys conducted by the Marine Monitoring Team in 2009.

## Appendix 5 – Site Summaries

Summaries are presented for each survey site. Within each summary, a representative photograph is shown with a map showing the site location in red. All of the following are described in the text.

- The site's location.
- Scores for all 9 variables used in the resilience analysis and the final resilience score and rank. Descriptions of the methods for each variable can be found in the main report, section 2; temperature variability refers to variability (standard deviation) in the summertime temperatures (between 1982 and 2011).
- The benthic community composition.
- The diversity of stony corals.
- the number of species of corals observed that: (a) were on the list of 82 in the October 2009 petition for endangered species status (23 of the 40 known to be in CNMI were observed during these surveys), and (b) were proposed by the NMFS in November, 2012 as 'threatened' (14 of 23) or 'listing status not warranted' (9 of 23). The one species known to be in CNMI listed as endangered, *Millepora foveolata*, was not seen during our surveys.
- The biomass of herbivorous fish and the most common functional groups of herbivorous fish observed.
- The size-class distribution of stony corals.
- The size-class distribution of two key herbivorous fish families – Scaridae and Acanthuridae.

Methods for calculating the resilience scores are contained in the report methods, including anchoring and normalizing the continuous values measured in the field and using desktop analysis. Within the summaries the relative terms high, medium and low refer to anchored scores of 0.8-1.0, 0.6-0.79, and <0.6, respectively. This means scores are high if values are >80% of the max value, medium if between 60 and 79% of the max value, and low if less than 60% of the max value. Tables and figures are presented to complement the text and support statements therein; these are standard for all summaries presented and are as follows:

Table 1 shows the raw and anchored scores for all resilience variables, the final resilience score and the rank out of 35.

Table 2 contains a list of the coral species observed that were on the original 2009 petition for endangered species status with the NMFS. A superscript 'T' and 'NW' are used for the classifications released in November of 2012 for '*threatened*' and 'endangered species listing *not warranted*'. This table is only shown if one of the relevant coral species was observed.

Figure 1 presents the benthic community composition as a pie chart.

Figure 2 is the size-class frequency distribution of hard corals.

Figure 3 shows the mean biomass of herbivorous fish functional groups designated by IUCN.

Figure 4 shows herbivore biomass at the site relative to all other sites.

Figures 5 and 6 are size-class frequency distributions for Scaridae and Acanthuridae, respectively.

The site summaries are presented in the order of highest to lowest resilience score – Forbidden Island's summary is shown first and the summary for Fishing Base Staghorn is presented last.

The site summary appendix is a separate document. The following contents list shows the page number for each of the respective site summaries.

## Rank 1/35: Forbidden Island

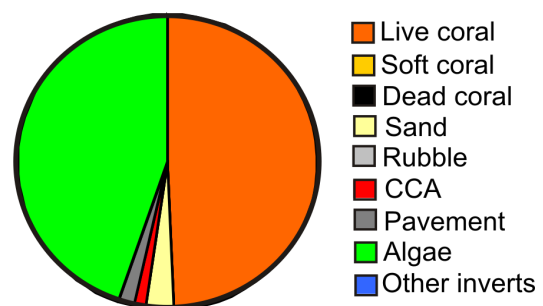

This is one of two sites surveyed located in the Forbidden Island Marine Sanctuary, a fully protected no-take area established in 2001. This survey site is located on the southern side of Forbidden Island. Forbidden Island gets its name for the difficult hike to access the island, along with the strong waves that can pose a danger to swimmers. This Forbidden Island site is a highly resilient site ranking first of all the sites with a resilience score of 0.84 (anchored to 1.00, the maximum possible score) (Table 1). Five of the nine variables received high

scores (0.8+): coral diversity, temperature variability, macroalgae cover, nutrient input, and fishing access. Although there are other sites with more variables that received high scores, this Forbidden Island site did not have any variables with anchored scores less than 0.59. Coral recruitment, bleaching resistance, and sedimentation received medium scores. Coral diversity at this site is 0.93 (Simpson's Index) and about 35% of the coral community here is susceptible to bleaching. The benthos environment is mostly comprised of live coral (49%) and algae (44.3%) with the remainder being soft corals, CCA (Crustose Coralline Algae), and pavement (bare substrate) (Fig. 1). Four of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 4 species, 3 were proposed in November 2012 as 'threatened' and 1 species was proposed as 'not warranted' by NMFS (Table 2). About three-quarters of the corals observed at Forbidden Island were small (<16 cm in diameter) (Fig. 2). Herbivore biomass is relatively high – 1.95 kg/100m<sup>2</sup> (rank 6/35, Fig. 3; score of 0.59) – and most herbivorous fish present were grazers (Fig. 4). The size-class frequency distribution of Scarids had a wider range than that of Acanthurids; Scarids ranged in length from 11-40 cm and all Acanthurids observed were less than 20 cm (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.93	0.96
Recruitment	9.75	0.68
Bleaching Resistance	64.99	0.73
Temperature variability	0.96	0.97
Herbivore biomass	1.95	0.59
Macroalgae cover*	0.00	1.00
Nutrient input*	2.46	0.91
Sedimentation*	1.57	0.70
Fishing pressure	1440	1.00
Resilience score		0.84
Final anchored resilience score (1/35)		1.00

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

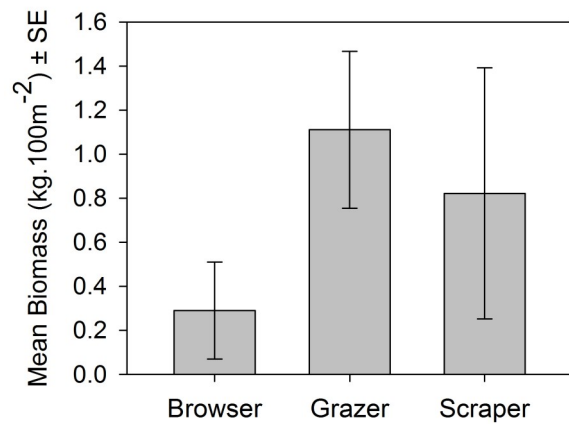

Species observed (4/24)
<i>Acropora vaughani</i> <sup>T</sup>
<i>Acropora verweyi</i> <sup>T</sup>
<i>Cyphastrea ocellina</i> <sup>NW</sup>
<i>Millepora tuberosa</i> <sup>T</sup>

**Figure 2.** Size-class frequency distribution for stony corals.

**Figure 4.** Proportion of the observed herbivorous fish community made up by three IUCN functional group classifications.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 2/35: Bird Island

This site is located within the Bird Island Marine Sanctuary, a fully protected no-take area established in 2000 that extends from the Grotto in the north to the Bird Island lookout point in the south. This site is a Marine Monitoring Team survey site. Bird Island has the second highest resilience score of 0.83 (anchored to 0.99) and is classified as a high resilience site. High coral diversity, temperature variability, and high herbivore biomass, along with low macroalgae cover, nutrient input and fishing access contribute to the high resilience of this site (Table 1). Most

of the benthos (70%) is made up of hard corals, with the remaining being algae, pavement (bare substrate), CCA, rubble and sand (Fig. 1). Eleven of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these eleven species, 7 species were proposed in November 2012 as 'threatened' and 4 species were proposed as 'not warranted' (Table 2). Corals at the site are mostly small (<16 cm) – more than half are less than 8 cm in diameter (Fig. 2). Herbivore biomass was greatest at this site (3.33 kg/100 m<sup>2</sup>, Fig. 3, rank 1/35) and most of the herbivorous fish community observed at the site are browsers (Fig. 4). The size class distributions of Acanthurids and Scarids are similar (Figs. 5 & 6). More than half of the fish in these families observed at the site were less than 20 cm in length. Invertebrates encountered include trochus and sea cucumbers (*Actinopyga miliaris*), though not in high densities. The reef at this site is unique in that the topography is very complex. Encrusting and small bushy corals grow here in a sort of patchwork quilt on large fingers of rock extending to the shallows (<5 m) and divided by deeper (15 m) water.

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.95	0.98
Recruitment	5.81	0.41
Bleaching Resistance	59.91	0.68
Temperature variability	0.98	0.99
Herbivore biomass	3.33	1.00
Macroalgae cover*	0.00	1.00
Nutrient input*	5.18	0.81
Sedimentation*	2.28	0.57
Fishing pressure	550	1.00
Resilience score		0.83
Final anchored resilience score (2/35)		0.99

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (11/24)
<i>Acanthastrea brevis</i> <sup>T</sup>
<i>Acropora palmerae</i> <sup>T</sup>
<i>Cyphastrea agassizi</i> <sup>NW</sup>
<i>Cyphastrea ocellina</i> <sup>NW</sup>
<i>Heliopora coerulea</i> <sup>NW</sup>
<i>Millepora tuberosa</i> <sup>T</sup>
<i>Montipora calculata</i> <sup>T</sup>
<i>Montipora lobulata</i> <sup>T</sup>
<i>Pocillopora danae</i> <sup>T</sup>
<i>Pocillopora elegans</i> <sup>T</sup>
<i>Turbinaria stellulata</i> <sup>NW</sup>

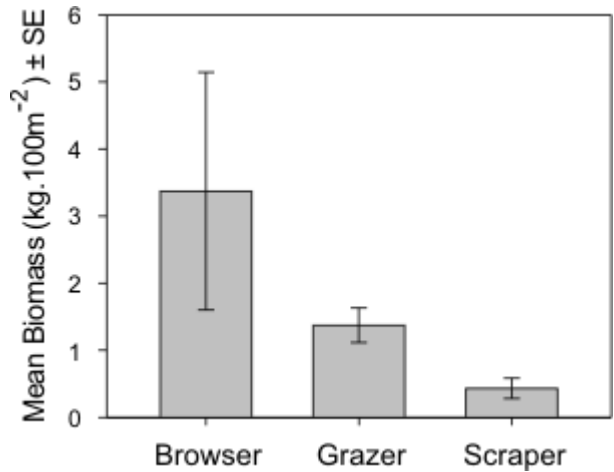

**Figure 3.** Herbivore biomass for the site (in red) amongst all sites surveyed.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 2.** Size-class frequency distribution for stony corals.

**Figure 4.** Proportion of the observed herbivorous fish community made up by three IUCN functional group classifications.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 3/35: Lanyas

This site is located within the Managaha Marine Conservation Area, which is a fully protected no-take area established in 2000. This track of reef is also home to one of Saipan's more popular surf spots. This site is a Marine Monitoring Team survey site. Lanyas has the third highest resilience score (0.82, anchored to 0.98) and is classified as a high resilience site. High coral diversity and temperature variability, and low macroalgae cover, nutrient input, and fishing access contributed to the high resilience score (Table 1). Bleaching resistance, recruitment and sedimentation had medium scores.

Of the nine variables in the analysis, only herbivore biomass had a low score, though many large fish were seen at the fringes of the survey area. The Simpson's Index of Diversity for corals was high at 0.94. 45% of the benthic substrate is live coral with mostly bare substrate and <5% of other invertebrates making up the remaining area (Fig. 1). Four of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 4 species, 3 species were proposed in November 2012 as 'threatened' and 1 species was proposed as 'not warranted' (Table 2). Almost all of the corals observed at Lanyas are very small (<8 cm in mean diameter) (Fig. 2). The biomass of herbivores at the site during the surveys was 1.18 kg/100m<sup>2</sup> (14/35, Fig. 3) and herbivorous fish observed at the site were mostly grazers (Fig. 4). Larger Scarids were observed, mostly 16-20 cm in length; the Acanthurids observed were small, 11-15 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.94	0.98
Recruitment	11.00	0.77
Bleaching Resistance	59.66	0.67
Temperature variability	0.96	0.97
Herbivore biomass	1.18	0.35
Macroalgae cover*	0.00	1.00
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	142	1.00
Resilience score		0.82
Final anchored resilience score (3/35)		0.98

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

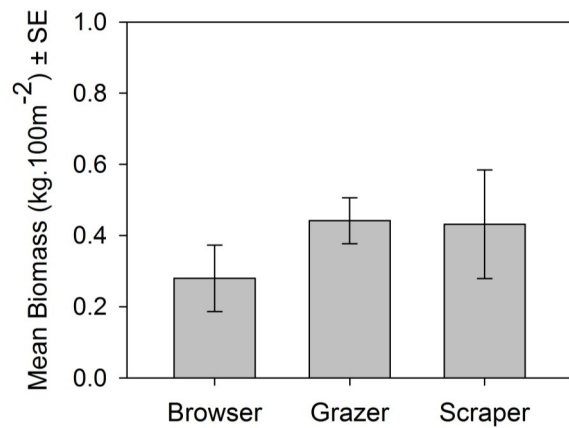

Species observed (4/24)
<i>Acropora vaughani</i> <sup>T</sup>
<i>Acropora verweyi</i> <sup>T</sup>
<i>Cyphastrea ocellina</i> <sup>NW</sup>
<i>Pocillopora danae</i> <sup>T</sup>

**Figure 2.** Size-class frequency distribution for stony corals.

**Figure 4.** Proportion of the observed herbivorous fish community made up by three IUCN functional group classifications.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 4/35: Nanasu Reef

Nanasu Reef is located on the windward side of Saipan, on the boundary of the Bird Island Conservation Area boundary. The majority of the eastern coast of Saipan has poor reef development due to high wave exposure, but Nanasu is one of the few exceptions. Nanasu Reef has a high resilience score of 0.80 (anchored to 0.95) and is ranked 4/35. Six of the nine variables included in the resilience analysis had high scores: coral diversity, temperature variability, herbivore biomass, macroalgae cover, nutrient input, and fishing access (Table 1). Bleaching resistance and sedimentation received medium scores, with just one variable (coral recruitment) receiving a low score. Coral diversity is high with a Simpson's Index of Diversity value of 0.92. The benthos at this site is diverse with algae (33.3%), live coral (23.7%), pavement (bare substrate) (23.3%), and rubble (16.7%) all having coverage greater than 15% (Fig. 1). Negligible amounts of sand, CCA, and invertebrate species make up the rest of the benthos. Seven of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 7 species, 6 species were proposed in November 2012 as 'threatened' and 1 species was proposed as 'not warranted' (Table 2). Corals ranged in diameter from <1 cm-32 cm, but more than half of the corals were recruits (<4 cm in diameter) (Fig. 2). Nanasu Reef has the second greatest amount of herbivore biomass at 3.01 kg/100m<sup>2</sup> (2/35, Fig. 3), and most herbivorous fish were identified as grazers (Fig. 4). Most members of the Scaridae family that were observed were 16-25 cm in length. The Acanthurids observed were slightly smaller with the majority being 11-20 cm (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.92	0.95
Recruitment	7.44	0.52
Bleaching Resistance	53.85	0.61
Temperature variability	0.99	1.00
Herbivore biomass	3.01	0.90
Macroalgae cover*	6.00	0.92
Nutrient input*	3.97	0.86
Sedimentation*	1.99	0.62
Fishing pressure	1429	0.81
Resilience score		0.80
Final anchored resilience score (4/35)		0.95

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 5/35: MMT Managaha MPA

This site is located in the Managaha Marine Conservation Area. The habitat here is primarily dominated by the coral *Isopora palifera*. Ranked 5<sup>th</sup> overall, the Managaha MPA has a resilience score of 0.79 (anchored to 0.94) and is classified as a high resilience site. Six of the nine variables included in the resilience analysis measured had high scores: coral diversity, bleaching resistance, temperature variability, macroalgae cover, nutrient input, and sedimentation (Table 1). Only sedimentation received a medium score, while coral recruitment and herbivore

biomass received low scores. Live corals account for 43.3% of the benthic environment and algae for 33.3% (Fig. 1). The rest of the benthos is made up of sand, rubble, CCA, and pavement (bare substrate). Seven of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 7 species, 6 species were proposed in November 2012 as ‘threatened’ and 1 species was proposed as ‘not warranted’ (Table 2). Most corals observed at the site are 2-16 cm (Fig. 2). The MPA had one of the highest herbivore biomass concentrations, 1.48 kg/100m<sup>2</sup> (7/35, Fig. 3). The majority of the herbivore fish community observed are grazers (Fig. 4). Acanthurids we observed had a wider size class frequency range than the Scarids with lengths ranging from <5-20 cm (Figs. 5 & 6). All Scarids observed were 16-20 cm in length.

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

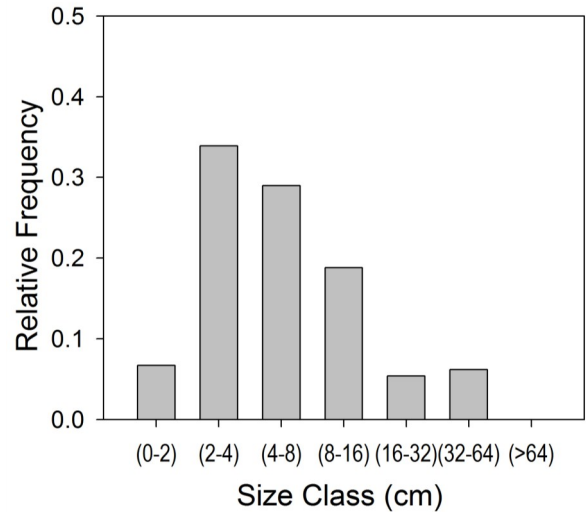

Variable	Raw Value	Anchored Score
Coral Diversity	0.79	0.82
Recruitment	7.58	0.53
Bleaching Resistance	71.23	0.81
Temperature variability	0.96	0.97
Herbivore biomass	1.48	0.44
Macroalgae cover*	9.33	0.87
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	12	1.00
Resilience score		0.79
Final anchored resilience score (5/35)		0.94

## Rank 6/35: Obyan Beach

The survey site at Obyan Beach is home to an ancient Chamorro *Latte* village, a popular picnic area, a surf break, and is a common dive site and turtle nesting beach. This site is a Marine Monitoring Team survey site. Obyan Beach is the sixth ranked site overall with a resilience score of 0.76 (anchored to 0.90) and is classified as a high resilience site. Five variables at Obyan Beach received high scores: coral diversity, coral recruitment, temperature variability, macroalgae cover, and nutrient input (Table 1). Coral recruitment and herbivore biomass both received medium scores, with just fishing access receiving a low score. Coral diversity is high – the Simpson’s Index of Diversity value is 0.90 (anchored score of 0.98). Obyan Beach supports a benthic environment of mostly pavement (bare substrate), but 39.7% is live coral and 1.3% CCA; no macroalgae was observed (Fig. 1). Nine of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 9 species, 7 species were proposed in November 2012 as ‘threatened’ and 2 species were proposed as ‘not warranted’ (Table 2). Most corals observed at Obyan Beach were 8 cm or less in diameter with only a few larger corals observed (Fig. 2). This site had the third highest concentration of herbivore biomass, 2.65 kg/100m<sup>2</sup> (Fig. 3), and most herbivorous fish present were scrapers (Fig. 4). The biomass ranking is probably inflated as the fish at this popular dive location exhibited behavior typical of fish used to being fed by divers. Of the Scarids and Acanthurids observed, more than half of both species were 16-20 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.95	0.98
Recruitment	13.50	0.94
Bleaching Resistance	59.27	0.67
Temperature variability	0.95	0.96
Herbivore biomass	2.65	0.79
Macroalgae cover*	0.00	1.00
Nutrient input*	4.41	0.84
Sedimentation*	2.10	0.60
Fishing pressure	54	0.03
Resilience score		0.76
Final anchored resilience score (6/35)		0.90

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 7/35: South Laolao

This is the most southerly site surveyed in Laolao Bay. The reef's location gives it unusually high wave exposure for sites within Laolao Bay. South Laolao is ranked 7/35 with a resilience score of 0.76 (anchored to 0.90) and is considered a high resilience site. Five of the nine variables: coral diversity, bleaching resistance, temperature variability, nutrient input, and fishing access received high scores (Table 1). Coral recruitment and macroalgae received medium scores with just herbivore biomass scoring low in the resilience assessment. Coral diversity is very high

with a Simpson's Index of Diversity value of 0.95 (anchored score of 0.99), but coral cover is low (<15%, Fig. 1). Algae is the major component of the benthic environment at this site, covering 45.6% of the substrate (Fig. 1). Pavement (bare substrate), CCA, and sand were also observed at the site. One of the coral species originally petitioned in 2009 for endangered species status was observed during these surveys. The species observed was proposed in November 2012 as 'not warranted' (Table 2). Corals are mostly very small (<8 cm in diameter). A few larger corals with diameters 16-32 cm were also observed (Fig. 2). Herbivore biomass is low relative to the other sites at 0.47 kg/100m<sup>2</sup> (28/35, Fig. 3) and the observed herbivore fish community was comprised of mostly grazers (Fig. 4). The Acanthurids observed at this site were 15 cm in length or smaller. Scarids were not observed at the site during these surveys (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.95	0.99
Recruitment	10.46	0.73
Bleaching Resistance	73.95	0.84
Temperature variability	0.95	0.96
Herbivore biomass	0.47	0.14
Macroalgae cover*	24.61	0.66
Nutrient input*	3.22	0.88
Sedimentation*	1.80	0.66
Fishing pressure	1671	0.94
Resilience score		0.76
Final anchored resilience score (7/35)		0.90

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 8/35: Laolao Bay East

Laolao Bay East is the easternmost site located in Laolao Bay. This site is one of the most popular fishing spots around Saipan. Laolao Bay East is ranked 8/35 with a resilience score of 0.75 (anchored to 0.89) and is classified as a high resilience site. Six of the nine variable included in the resilience analysis had high scores: coral diversity, coral recruitment, bleaching resistance, temperature variability, macroalgae cover, nutrient input (Table 1). Sedimentation was the only variable to receive a medium score, while herbivore biomass and fishing access received low scores. Coral assemblages at Laolao Bay East were highly diverse (0.93

for Simpson's Index of Diversity) and had one of the highest ('best') scores for bleaching susceptibility with less than 20% of the community susceptible to bleaching. Most of the substrate is made up of live coral (22.3%) and macroalgae (50.3%) (Fig. 1). Sand, rubble, CCA, pavement (bare substrate), and invertebrates are also present at the site in lesser amounts. Seven of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 7 species, 3 species were proposed in November 2012 as 'threatened' and 4 species were proposed as 'not warranted' (Table 2). Corals at this site are mostly very small (<8 cm in diameter), but a few larger corals were also observed (Fig. 2). Herbivore biomass is 1.25 kg/100m<sup>2</sup> (12/35, Fig. 3), and the observed herbivore fish community was mostly comprised of grazers (Fig. 4). The size-class frequencies for Scarids and Acanthurids differ: all Scarids were found to be <20 cm in length, and Acanthurids >11 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.93	0.96
Recruitment	14.31	1.00
Bleaching Resistance	81.79	0.92
Temperature variability	0.96	0.97
Herbivore biomass	1.25	0.37
Macroalgae cover*	1.00	0.99
Nutrient input*	3.67	0.87
Sedimentation*	1.92	0.64
Fishing pressure	20	0.01
Resilience score		0.75
Final anchored resilience score (8/35)		0.89

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (4/24)
<i>Cyphastrea ocellina</i> <sup>NW</sup>
<i>Pavona bipartita</i> <sup>NW</sup>
<i>Pocillopora elegans</i> <sup>T</sup>
<i>Turbinaria reniformis</i> <sup>NW</sup>

**Figure 2.** Size-class frequency distribution for stony corals.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 9/35: Agingan Point

Agingan Point is the southwestern most point on Saipan. An outfall pipe from a sewage treatment plant is located at the point, 90 feet deep and 90 feet away from the coast line. Despite proximity to the pipe, Agingan Point has the ninth highest resilience score (0.72, anchored to 0.86) and is classified as a high resilience site. Although the site received low scores for herbivore biomass and fishing access, the site scored high in five of the 9 variables used in the resilience analysis: coral diversity, coral recruitment, temperature variability, nutrient input, and macroalgae (Table 1). Bleaching resistance and sedimentation both received medium scores. The Simpson's Index of Diversity value for coral diversity is 0.91. Turfing algae covers much of the substrate at the site (46.7%), though coral cover is a close second with 35.3% (Fig. 1). Three of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. All 3 of these species were proposed in November 2012 as 'threatened' (Table 2). A few larger corals were found at this site, but most corals were very small (<8 cm in diameter) (Fig. 2). Herbivore biomass is low, 0.67 kg/100m<sup>2</sup> (anchored score of 0.20, 21/35, Fig. 3) and the majority of herbivorous fishes observed were grazers (Fig. 4). All Scarids and most Acanthurids were 11-15 cm in length, but some Acanthurids <11 cm were also observed (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.91	0.94
Recruitment	13.50	0.94
Bleaching Resistance	66.80	0.76
Temperature variability	0.97	0.98
Herbivore biomass	0.67	0.20
Macroalgae cover*	0.00	1.00
Nutrient input*	2.28	0.92
Sedimentation*	1.51	0.71
Fishing pressure	130	0.07
Resilience score		0.72
Final anchored resilience score (9/35)		0.86

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 10/35: Oleai Rocks

Oleai Rocks is located on the western side of Saipan. Dive operators have been using this area as a back-up to more popular sites like Ice Cream or Dimple. Oleai Rocks is a high resilience site with a resilience score of 0.72 (anchored to 0.86). This site scored high for four of the 9 variables used in the resilience analysis: coral diversity, temperature variability, macroalgae cover, and nutrient input (Table 1). Coral recruitment, bleaching resistance, and sedimentation received medium scores while herbivore biomass and fishing access received low scores.

Coral species diversity was high with a Simpsons Index of Diversity value of 0.92. The majority of the substrate at this site at the time of surveys is pavement (bare substrate) (42%), and coral cover (30.3%) (Fig. 1). One of the coral species originally petitioned in 2009 for endangered species status was observed during these surveys. This species was proposed in November 2012 as ‘threatened’ (Table 2). Corals observed ranged in diameter from <1 cm to 64 cm, but most were recruits (<4 cm in diameter) (Fig. 2). Herbivore biomass is 1.47 kg/100m<sup>2</sup> (anchored score of 0.44, 8/35, Fig. 3) and most herbivorous fish at the site are scrapers (Fig. 4). More than half of the Scarids and Acanthurids observed were 11-20 cm in length, but some larger and smaller Scarids were observed (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.92	0.96
Recruitment	10.69	0.75
Bleaching Resistance	58.52	0.66
Temperature variability	0.94	0.95
Herbivore biomass	1.47	0.44
Macroalgae cover*	0.00	1.00
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	100	0.06
Resilience score		0.72
Final anchored resilience score (10/35)		0.86

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (1/24)
<i>Montipora caliculata</i> <sup>T</sup>

**Figure 2.** Size-class frequency distribution for stony corals.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 11/35: Laolao Bay Mids

Laolao Bay Mids is located within central Laolao Bay. This site lies within the Laolao Bay Sea Cucumber Sanctuary, which was established to address overharvesting issues. Laolao Bay Mids is ranked 11/35 with a resilience score of 0.72 (anchored to 0.85) and is classified as a high resilience site. Four of the nine variables included in the resilience analysis received high scores: coral diversity, temperature variability, macroalgae cover, and nutrient input (Table 1). Bleaching resistance, herbivore biomass, and sedimentation received medium scores, with just two variables (coral recruitment and fishing access) receiving low scores. More than a

third of the coral community at Laolao Bay Mids is susceptible to bleaching, though as with most other surveyed sites coral diversity is high (0.91, Simpson's Index of Diversity). Algae covers 73% of the substrate at this site and live coral only 14.5% (Fig. 1). The rest of the substrate is covered by sand, rubble, CCA, and other invertebrates. Six of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 6 species, 3 species were proposed in November 2012 as 'threatened' and 3 species were proposed as 'not warranted' (Table 2). The majority of corals observed here were very small (<8 cm or less in diameter (Fig. 2). Laolao Bay Mids has the fifth highest concentration of herbivore biomass of all the sites observed: 1.98 kg/100m<sup>2</sup> (Fig. 3). Most herbivorous fish observed were browsers (Fig. 4). The majority of Scarids and Acanthurids observed were between 16 cm and 20 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.91	0.95
Recruitment	8.44	0.59
Bleaching Resistance	63.76	0.72
Temperature variability	0.96	0.97
Herbivore biomass	1.98	0.60
Macroalgae cover*	0.50	0.99
Nutrient input*	2.83	0.90
Sedimentation*	1.68	0.68
Fishing pressure	85	0.05
Resilience score		0.72
Final anchored resilience score (11/35)		0.85

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (2/24)
<i>Acanthastrea brevis</i> <sup>T</sup>
<i>Pocillopora danae</i> <sup>T</sup>

**Figure 2.** Size-class frequency distribution for stony corals.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 12/35: North Dakota

North Dakota reef is located in the southern half of LaoLao Bay. North Dakota reef is located near the abandoned estate of Larry Hilbloom, the estranged millionaire who went missing in the 1980s. North Dakota is the twelfth ranked site and is considered a high resilience site with a resilience score of 0.71 (anchored to 0.86). This site received high scores for four of the 9 variables included in the resilience analysis; coral diversity, temperature variability, macroalgae cover, and nutrient input (Table 1). Coral recruitment, bleaching resistance, and sedimentation received medium scores, while just two variables, fishing access and herbivore biomass received low scores. About a third of the coral community at North Dakota is susceptible to bleaching. Coral diversity was high with a Simpson's Index of Diversity of 0.94. The substrate is made up of roughly a third pavement (bare substrate), a third live coral, and a third made up of algae, sand and some CCA (Fig. 1). All of the algae present was turf algae with no recorded macroalgae. Four of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 4 species, 3 species were proposed in November 2012 as 'threatened' and 1 species was proposed as 'not warranted' (Table 2). Coral size at this site ranged from <1-32 cm with most corals recruit-size (<4 cm) (Fig. 2). Herbivore biomass concentration is 0.65 kg/100m<sup>2</sup> (22/35, Fig. 3), and most of the herbivorous fish observed are grazers or scrapers with only a few browsers observed (Fig. 4). Some large (36-40 cm) Scarids were observed (Fig. 5). More than 75% of the Acanthurids observed were <10 cm in length (Fig. 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.94	0.98
Recruitment	10.31	0.72
Bleaching Resistance	64.53	0.73
Temperature variability	0.96	0.97
Herbivore biomass	0.65	0.20
Macroalgae cover*	0.00	1.00
Nutrient input*	3.97	0.86
Sedimentation*	1.99	0.62
Fishing pressure	616	0.35
Resilience score		0.71
Final anchored resilience score (12/35)		0.85

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 13/35: Old Man By the Sea

One of the secluded pocket beaches on Saipan's eastern coast, Old Man by the Sea is a popular site amongst both locals and visitors. A rock formation resembles the profile of a man when viewed at the proper angle. Ranked thirteenth, Old Man By the Sea has a resilience score of 0.71 (anchored to 0.84) and is classified as a high resilience site. Despite the high resilience of the site, just three variables received high scores: coral diversity, temperature variability and macroalgae cover (Table 1). Bleaching resistance, nutrient input, and fishing access received medium scores while coral recruitment, herbivore biomass, and sedimentation all scored low. Coral diversity is above average (0.85) with a Simpson's Index of Diversity of 0.94. Almost 50% (48.7%) of the substrate is covered by live coral (Fig. 1). Algae, pavement, rubble, sand, and invertebrates were also observed. Six of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 6 species, 5 species were proposed in November 2012 as 'threatened' and 1 species was proposed as 'not warranted' (Table 2). The size class frequency of coral diameter ranges from >1 cm to 64 cm, but most corals observed are small (<16 cm) (Fig. 2). Herbivore biomass is 1.27 kg/100m<sup>2</sup> (11/35, Fig. 3) and the herbivorous fish community is mostly comprised of grazers (Fig. 4). More than half of both Scarids and Acanthurids observed range from 11-20 cm in length (Figs. 5 & 6). Both fish families also had a few fish <10 cm in length and some Acanthurids larger than 20 cm were observed (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.94	0.97
Recruitment	4.75	0.33
Bleaching Resistance	69.79	0.79
Temperature variability	0.94	0.95
Herbivore biomass	1.27	0.38
Macroalgae cover*	6.00	0.92
Nutrient input*	7.16	0.74
Sedimentation*	2.68	0.49
Fishing pressure	1397	0.79
Resilience score		0.71
Final anchored resilience score (13/35)		0.84

## Rank 14/35: Point Break Reef

Point Break Reef is one of the southeastern reefs of Saipan. The reef here is adjacent to Saipan's most consistently breaking 'wave' – the Point Break flowrider mechanical wave at the Pacific Islands Resort. Ranked 14/35, Point Break Reef has a resilience score of 0.71 (anchored to 0.84) and is classified as a high resilience site. Coral diversity, temperature variability, macroalgae cover, and nutrient input, all received high scores, while coral recruitment, bleaching resistance, and sedimentation received medium scores (Table 1). Fishing access and herbivore biomass both received low scores. Coral assemblages at Point Break Reef are diverse and have a Simpson's Index of Diversity of 0.92, though 38.02% of the coral community was found to be susceptible to bleaching. The substrate at Point Break Reef consists of turf algae (41.3%) and live coral (24%) with sand, rubble, CCA, and pavement making up the remaining area (Fig. 1). Two of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Both of these coral species were proposed in November 2012 as 'threatened' (Table 2). Almost all corals observed were very small (<8 cm) (Fig. 2). The overall herbivore biomass concentration of the site is 0.90 kg/100m<sup>2</sup> (17/35) (Fig. 3). More than half of the herbivorous fish observed were grazers (Fig. 4). All Scarids and more than half of the Acanthurids observed ranged from 11-15 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.92	0.95
Recruitment	10.92	0.76
Bleaching Resistance	61.98	0.70
Temperature variability	0.95	0.96
Herbivore biomass	0.90	0.27
Macroalgae cover*	0.00	1.00
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	119	0.07
Resilience score		0.75
Final anchored resilience score (14/35)		0.84

## Rank 15/35: Pau Pau

Pau Pau is located on the north-eastern portion of Saipan's barrier reef. The lagoon area within the site is a common site to see black-tip shark pups. Pau Pau has a resilience score of 0.71 (anchored to 0.84) and is considered a high resilience site. Coral diversity, temperature variability, macroalgae cover, and nutrient input all received high scores, while coral recruitment, bleaching resistance, and sedimentation received medium scores (Table 1). The only two variables to receive low scores were herbivore biomass and fishing access.

Coral diversity was relatively high with a Simpson's Index of Diversity of 0.94, above the survey average (0.85). The substrate at this site is mostly pavement (bare substrate) (76.7%) with 20% live coral and 1% or less of sand, algae, and invertebrates (Fig. 1). Three of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. All 3 of these were proposed in November 2012 as 'threatened' (Table 2). The majority of corals observed were very small (<8 cm) (Fig. 2). Herbivore biomass was 1.07 kg/100m<sup>2</sup> (15/35, Fig. 3) and most of the herbivorous fish community observed were grazers (Fig. 4). Most Scarids and Acthurids observed were 11-15 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.94	0.97
Recruitment	11.06	0.77
Bleaching Resistance	54.07	0.61
Temperature variability	0.96	0.97
Herbivore biomass	1.07	0.32
Macroalgae cover*	0.00	1.00
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	107	0.06
Resilience score		0.71
Final anchored resilience score (15/35)		0.84

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 16/35: Achu Dangkulu

Achu Dangkulu is located on the northwestern portion of Saipan's barrier reef. The dominant feature – a rock formation exposed at low tide – is a traditional fishing spot for the community of Tanapag village. Achu Dangkulu has a resilience score of 0.70 (anchored to 0.84) and this 16<sup>th</sup> ranked site is considered a high resilience site. High coral diversity and temperature variability contributed to the overall high resilience score (Table 1). Coral recruitment, bleaching resistance, and sedimentation received medium scores, while fishing access and herbivore biomass received low scores.

Achu Dangkulu has high coral diversity surveyed with a Simpson's Index of Diversity of 0.94. The substrate is comprised of almost equal parts live coral (26%), sand (27.3%), and algae (27%); CCA and pavement account for the remaining area (Fig. 1) Four of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. All 4 of these species were proposed in November 2012 as 'threatened' (Table 2). The majority of corals observed at the site are very small (<8 cm) in diameter (Fig. 2). Herbivore biomass at the site is amongst the lowest of all the surveyed sites at 0.30 kg/100m<sup>2</sup> (32/35, Fig. 3). Most of the herbivorous fish observed were scrapers (Fig. 4). Scarids were not observed during the surveys. Almost all of the Acanthurids observed were <15 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.94	0.98
Recruitment	8.94	0.62
Bleaching Resistance	67.74	0.77
Temperature variability	0.96	0.97
Herbivore biomass	0.30	0.09
Macroalgae cover*	0.00	1.00
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	443	0.25
Resilience score		0.70
Final anchored resilience score (16/35)		0.84

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (4/24)
<i>Acropora vaughani</i> <sup>T</sup>
<i>Acropora verweyi</i> <sup>T</sup>
<i>Montipora caliculata</i> <sup>T</sup>
<i>Pocillopora danae</i> <sup>T</sup>

**Figure 2.** Size-class frequency distribution for stony corals.

**Figure 4.** Proportion of the observed herbivorous fish community made up by three IUCN functional group classifications.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 17/35: Boy Scout

Boy Scout is located on the southern coast of Saipan. This site is a Marine Monitoring Team survey site. Boy Scout is a popular dive site and is named for the annual trip that the local Boy Scout troops take to visit the beach. This high resilience site is ranked 17/35 and has a resilience score of 0.70 (anchored to 0.83). Five variables received high scores: coral diversity, bleaching resistance, temperature variability, macroalgae cover, and nutrient input (Table 1). Coral recruitment and sedimentation had medium scores

and herbivore biomass and fishing access received low scores. Coral diversity is above average (0.85) with a Simpson's Index of Diversity value of 0.94. The substrate is made up of live coral (25%), sand (20.5%), CCA (23.2%), and rubble (14.8%) (Fig. 1). Turf algae (1.3%) and invertebrates (1.5%) were also observed. Nine of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 9 species, 7 species were proposed in November 2012 as 'threatened' and 2 species were proposed as 'not warranted' (Table 2). Most corals observed are very small (<8 cm), but some corals larger than 16 cm in diameter were observed (Fig. 2). Herbivore biomass at Boy Scout is 1.19 kg/100m<sup>2</sup> (13/35, Fig. 3). Grazers, scrapers and browsers were all observed at the site (Fig. 4). All Scarids and most Acanthurids observed were 16-20 cm in length, but a few Acanthurids <15 cm were observed as well (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.94	0.98
Recruitment	10.06	0.70
Bleaching Resistance	70.68	0.80
Temperature variability	0.95	0.96
Herbivore biomass	1.19	0.36
Macroalgae cover*	0.00	1.00
Nutrient input*	4.20	0.85
Sedimentation*	2.05	0.61
Fishing pressure	57	0.03
Resilience score		0.70
Final anchored resilience score (17/35)		0.83

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

**Figure 4.** Proportion of the observed herbivorous fish community made up by three IUCN functional group classifications.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 18/35: South Dakota

The South Dakota reef is located within Laolao Bay, in the DanDan watershed. The survey site was affectionately named South Dakota due to its resemblance to the rolling hills of the state. South Dakota is the 18th ranked site and is classified as a high resilience site (0.69, anchored to 0.82). Of the nine variables used in the resilience analysis, five of the variables received high scores: coral diversity, bleaching resistance, temperature variability, nutrient input, and fishing access (Table 1). Sedimentation was the only variable to receive a medium score, while coral recruitment and herbivore biomass received low scores. Coral diversity at this site is above average (0.85); the Simpson's Index of Diversity value is 0.95. South Dakota received the fourth highest score for bleaching resistance with less than 20% of the coral community susceptible to bleaching. The substrate at the site is covered mostly by algae (48.7%) and corals (31.3%) (Fig. 1). Three of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 3 species, 2 species were proposed in November 2012 as 'threatened' and 1 species was proposed as 'not warranted' (Table 2). Most corals at the site are small (<16 cm in diameter) though some corals larger than 16cm were observed (Fig. 2). Herbivore biomass at the time of surveys is 0.51 kg/100m<sup>2</sup> (25/35. Fig. 3) and most herbivorous fish observed were grazers (Fig. 4). The majority of Scarids and Acanthurids observed were 15 cm in length or smaller. A few Acanthurids larger than 16 cm in length were observed (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.95	0.98
Recruitment	4.81	0.34
Bleaching Resistance	80.95	0.92
Temperature variability	0.95	0.96
Herbivore biomass	0.51	0.15
Macroalgae cover*	33.67	0.54
Nutrient input*	3.25	0.88
Sedimentation*	1.80	0.66
Fishing pressure	1405	0.79
Resilience score		0.69
Final anchored resilience score (18/35)		0.82

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 19/35: Wing Beach

Wing Beach is located on the northwest side of Saipan and is a Marine Monitoring Team survey site. On calm days, divers often see turtles and a humpback whale was seen from the surface during these surveys. Wing Beach is ranked nineteenth overall with a resilience score of 0.69 (anchored to 0.82) and is classified as a high resilience site. Coral diversity, temperature variability, macroalgae cover, and nutrient input all received high scores (Table 1). Coral recruitment and sedimentation received medium scores while

bleaching resistance, herbivore biomass, and fishing access all received low scores. Coral diversity is high at the site; the Simpson's Index of Diversity value is 0.84 (anchored to 0.98). More than half of the substrate (54%) was covered by live coral. Roughly a third of the remaining substrate was covered by pavement (bare substrate). The remaining substrate was made up by soft corals, rubble, CCA, algae and other invertebrates (Fig. 1). Nine of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 9 species, 6 species were proposed in November 2012 as 'threatened' and 3 species were proposed as 'not warranted' (Table 2). More than half of the corals observed at this site were recruits (<4 cm in diameter) (Fig. 2). A few corals >16 cm in mean diameter were also observed as well (Fig. 2). Herbivore biomass is 0.57 kg/100m<sup>2</sup> (24/35, Fig. 3). Most herbivorous fish observed were grazers (Fig. 4). Most Scarids observed were 16-20 cm in length. Most Acanthurids ranged from 11-15 cm (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.94	0.98
Recruitment	10.88	0.76
Bleaching Resistance	50.59	0.57
Temperature variability	0.98	0.99
Herbivore biomass	0.57	0.17
Macroalgae cover*	0.00	1.00
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	139	0.08
Resilience score		0.69
Final anchored resilience score (19/35)		0.82

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (9/24)
<i>Acropora aculeus</i> <sup>T</sup>
<i>Acropora vaughani</i> <sup>T</sup>
<i>Acropora verweyi</i> <sup>T</sup>
<i>Cyphastrea ocellina</i> <sup>NW</sup>
<i>Millepora tuberosa</i> <sup>T</sup>
<i>Pavona venosa</i> <sup>NW</sup>
<i>Pocillopora danae</i> <sup>T</sup>
<i>Pocillopora elegans</i> <sup>T</sup>
<i>Turbinaria reniformis</i> <sup>NW</sup>

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 20/35: Lighthouse Reef

The Lighthouse Reef is located within the Lighthouse Reef Trochus Sanctuary, which was established in 1981 to create a reservoir of high level trochus productivity. Trochus are now protected throughout the CNMI. With a resilience score of 0.69 (anchored to 0.82), Lighthouse reef is the 20<sup>th</sup> ranked site but is considered to be a high resilience site. This site received high scores for coral diversity, bleaching resistance, temperature variability, macroalgae cover, and nutrient input (Table 1). Sedimentation was the only factor to receive a medium score, while coral recruitment, herbivore biomass, and fishing access all received low scores.

Coral diversity is extremely high with a Simpson's Index of Diversity of 0.99, the third highest of all sites. The substrate is made up of 72% live coral (Fig. 1). Six of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. All 6 of these species were proposed in November 2012 as 'threatened' (Table 2). A few larger corals ranging in diameter from 16-64 cm were observed at this site, but most corals were very small (<8 cm) (Fig. 2). The herbivore biomass concentration at this site was 1.02 kg/100m<sup>2</sup> (16/35, Fig. 3) and most herbivorous fish present were grazers; only a few scrapers and browsers were observed (Fig. 4). The size-class frequency distributions were similar for Scaridae and Acanthuridae; for both families more than half of the fish observed were 11-15 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.95	0.99
Recruitment	6.42	0.45
Bleaching Resistance	71.85	0.81
Temperature variability	0.94	0.95
Herbivore biomass	1.02	0.31
Macroalgae cover*	0.00	1.00
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	38	0.02
Resilience score		0.69
Final anchored resilience score (20/35)		0.82

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (6/24)
<i>Acropora vaughani</i> <sup>T</sup>
<i>Acropora verweyi</i> <sup>T</sup>
<i>Millepora tuberosa</i> <sup>T</sup>
<i>Montipora caliculata</i> <sup>T</sup>
<i>Pocillopora danae</i> <sup>T</sup>
<i>Pocillopora elegans</i> <sup>T</sup>

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 21/35: Ladder Beach

Ladder Beach is located on the southern coast of Saipan. Ladder Beach is a popular beach for campers. Ladder Beach, ranked 21/35, has a resilience score of 0.69 (anchored to 0.82) and is classified as a high resilience site (Table 1). A sleeping white tip reef shark was seen at the site during these surveys. Coral diversity and temperature variability received high scores. Coral recruitment, bleaching resistance, and sedimentation all received medium scores. Herbivore biomass, fishing access, macroalgae cover and nutrient input received low scores. Ladder Beach has the highest coral diversity of all the sites surveyed (Simpson's Index of Diversity value of 0.96). The benthos is mostly comprised of live coral (34%) and sand (34%), but CCA, pavement, and algae are also present (Fig. 1). Six of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 6 species, 5 species were proposed in November 2012 as 'threatened' and 1 species was proposed as 'not warranted' (Table 2). Corals at this site are mostly very small with more than half <8 cm in diameter, but a few large (>16 cm diameter) corals were also seen (Fig. 2). The herbivore biomass at Ladder Beach is 0.48 kg/100m<sup>2</sup> (27/35, Fig. 3). Browsers, grazers and scrapers were seen, albeit in low densities (Fig. 4). Scarids observed ranged from 11-20 cm in length and Acanthurids ranged from 16-200 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.96	1.00
Recruitment	10.19	0.71
Bleaching Resistance	54.15	0.61
Temperature variability	0.95	0.96
Herbivore biomass	0.48	0.14
Macroalgae cover*	0.00	1.00
Nutrient input*	2.34	0.92
Sedimentation*	1.53	0.71
Fishing pressure	223	0.13
Resilience score		0.69
Final anchored resilience score (21/35)		0.82

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (6/24)
<i>Acropora vaughani</i> <sup>T</sup>
<i>Acropora verweyi</i> <sup>T</sup>
<i>Cyphastrea ocellina</i> <sup>NW</sup>
<i>Millepora tuberosa</i> <sup>T</sup>
<i>Montipora caliculata</i> <sup>T</sup>
<i>Pocillopora danae</i> <sup>T</sup>

**Figure 2.** Size-class frequency distribution for stony corals.

**Figure 3.** Herbivore biomass for the site (in red) amongst all sites surveyed.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 22/35: MMT Outside Grand Hotel

The MMT Outside Grand Hotel is ranked 22nd overall with a resilience score (0.68, anchored to 0.82) that just classifies it as a high resilience site. This site is a Marine Monitoring Team survey site. Five of the nine variables used in the resilience analysis received high scores; coral diversity, temperature variability, macroalgae cover, and nutrient input (Table 1). Bleaching resistance and sedimentation received medium scores, while coral recruitment, herbivore biomass, and fishing access all received low scores. About a third of the coral community found at the site is susceptible to bleaching. Coral diversity was high with a Simpson's Index of Diversity value of 0.95. No macroalgae were observed on the substrate, which was comprised of mostly live coral and pavement with less than a third of the site covered with turf algae, other invertebrates, sand, rubble, and CCA (Fig. 1). Seven of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 7 species, 5 species were proposed in November 2012 as 'threatened' and 2 species were proposed as 'not warranted' (Table 2). A few larger corals, 16-64 cm, were observed at this site. Most corals were very small (<8 cm in diameter) (Fig. 2). Herbivorous biomass concentration is 0.77 kg/100m<sup>2</sup> (20/35, Fig. 3) and most herbivorous fishes observed were grazers (Fig. 4). Most Scarids and Acanthurids ranged in length from 11-20 cm, but a few smaller (<11 cm) Acanthurids were observed as well (Figs. 5 & 6).

No macroalgae were observed on the substrate, which was comprised of mostly live coral and pavement with less than a third of the site covered with turf algae, other invertebrates, sand, rubble, and CCA (Fig. 1). Seven of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 7 species, 5 species were proposed in November 2012 as 'threatened' and 2 species were proposed as 'not warranted' (Table 2). A few larger corals, 16-64 cm, were observed at this site. Most corals were very small (<8 cm in diameter) (Fig. 2). Herbivorous biomass concentration is 0.77 kg/100m<sup>2</sup> (20/35, Fig. 3) and most herbivorous fishes observed were grazers (Fig. 4). Most Scarids and Acanthurids ranged in length from 11-20 cm, but a few smaller (<11 cm) Acanthurids were observed as well (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.95	0.98
Recruitment	6.93	0.48
Bleaching Resistance	69.66	0.79
Temperature variability	0.95	0.96
Herbivore biomass	0.77	0.23
Macroalgae cover*	0.00	1.00
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	113	0.06
Resilience score		0.68
Final anchored resilience score (22/35)		0.82

**Figure 1.** Proportion of the substrate covered by 9 groups.

## Rank 23/35: Elbow Reef

The Elbow Reef survey site is located just outside the the Managaha Marine Conservation Area. This part of the barrier reef surrounding the Saipan lagoon has high wave exposure and is home to very strong currents. Elbow Reef has the 23rd highest resilience score, 0.68 (anchored to 0.82), and is the lowest ranked of the sites considered to have high resilience. Temperature variability, nutrient input, coral diversity and macroalgae cover all received high scores (Table 1). Bleaching resistance and sedimentation

both received medium scores, while coral recruitment, herbivore biomass, and fishing access scored low at this site. Coral diversity is high at the site with a Simpson's Index of Diversity value of 0.96. The substrate was comprised of turf algae (64.3%) and live coral (23.7%) (Fig. 1). Three of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. All 3 of these species were proposed in November 2012 as 'threatened' (Table 2). The majority of corals seen are recruits (<4 cm) (Fig. 2). Herbivore biomass at the site is 0.36 kg/100m<sup>2</sup> (31/35, Fig. 3). Most of the herbivorous fish observed were grazers and scrapers (Fig. 4). Scarids were not observed during these surveys and almost all Acanthurids observed were <15cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.96	1.00
Recruitment	6.69	0.47
Bleaching Resistance	62.98	0.71
Temperature variability	0.96	0.97
Herbivore biomass	0.36	0.11
Macroalgae cover*	0.00	1.00
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	448	0.25
Resilience score		0.68
Final anchored resilience score (23/35)		0.82

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 24/35: Oleai Staghorn

Oleai Staghorn is located in the central part of the Saipan lagoon. The site was severely devastated by a bleaching event in 2000. The resilience score at Oleai Staghorn is 0.66 (anchored to 0.79) and is the highest scoring medium resilience site. Bleaching resistance, temperature variability, macroalgae cover, and nutrient input, all received high scores (Table 1). Coral diversity, herbivore biomass, and sedimentation all received medium scores. Coral recruitment and fishing access received low scores. This site is one of the least

diverse in terms of coral species, though it actually has the highest possible score for bleaching resistance with just over 10% of the coral assemblage susceptible to bleaching. Coral cover at the site though is very low (3.3%); most of the substrate is made up of pavement (bare substrate) (Fig. 1). Algae, sand, and invertebrates were also observed but made up less than 15% of the substrate. One of the coral species originally petitioned in 2009 for endangered species status was observed during these surveys. This species was proposed in November 2012 as 'threatened' (Table 2). More than three-quarters of corals observed were recruits (<4 cm in diameter). A few corals >32 cm in diameter were observed (Fig. 2). Though this site experiences the highest fishing access, Oleai Staghorn had the fourth greatest herbivore biomass (2.06 kg/100m<sup>2</sup>, Fig. 3). The herbivore fish community was mainly comprised of scrapers (Fig. 4). Scarids and Acanthurids have similar size-class frequencies. Most of the individuals in these families were 15 cm or smaller, but a few Scarids 16-20 cm were also observed (Figs. 5 & 6). This area appeared to be a nursery for many of the lagoon fish species.

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.69	0.72
Recruitment	2.50	0.17
Bleaching Resistance	88.46	1.00
Temperature variability	0.94	0.95
Herbivore biomass	2.06	0.62
Macroalgae cover*	11.33	0.84
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	7	0.00
Resilience score		0.66
Final anchored resilience score (24/35)		0.79

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (1/24)
<i>Acropora aspera</i> <sup>T</sup>

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 25/35: Coral Ocean Point

Coral Ocean Point is located on the southern shores of Saipan. This site is a Marine Monitoring Team survey site. This site, named for the golf course resort adjacent to the reef, is ranked 25/35, has a resilience score of 0.65 (anchored to 0.77) and is classified as a medium resilience site. Four of the nine variables used in the resilience analysis scored high in the resilience assessment: coral diversity, temperature variability, macroalgae cover, and nutrient input (Table 1). Coral recruitment was the only variable to receive a medium score, while bleaching resistance, herbivore biomass, sedimentation, and fishing access all received low scores.

Coral Ocean Point had the second highest coral diversity (Simpsons Index of Diversity value of 0.96) of the sites surveyed. The substrate is made up primarily of corals (57.3%) and algae (36.7%) (Fig. 1). Lesser amount of sand and pavement are present. Thirteen of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 13 species, 9 species were proposed in November 2012 as ‘threatened’ and 4 species were proposed as ‘not warranted’ (Table 2). This site has a wide distribution of coral size with diameter measurements ranging from less than 1 cm to 64 cm, but most corals are recruits (<4cm) (Fig. 2). Herbivore biomass is 0.65 kg/100m<sup>2</sup> (23/35, Fig. 3) and the herbivorous fish community is dominated by grazers (Fig. 4). At this site Scarids were found to be mostly larger than Acanthurids; the majority of Scarids were 16-20 cm in length, and almost all of the Acanthurids observed were 11-15 cm (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.96	1.00
Recruitment	9.50	0.66
Bleaching Resistance	51.36	0.58
Temperature variability	0.95	0.96
Herbivore biomass	0.65	0.20
Macroalgae cover*	0.00	1.00
Nutrient input*	5.30	0.81
Sedimentation*	2.30	0.56
Fishing pressure	103	0.06
Resilience score		0.65
Final anchored resilience score (25/35)		0.77

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (13/24)
<i>Acropora aculeus</i> <sup>T</sup>
<i>Acropora paniculata</i> <sup>T</sup>
<i>Acropora verweyi</i> <sup>T</sup>
<i>Alveopora fenestrata</i> <sup>T</sup>
<i>Heliopora coerulea</i> <sup>NW</sup>
<i>Leptoseris incrustans</i> <sup>NW</sup>
<i>Millepora tuberosa</i> <sup>T</sup>
<i>Montipora caliculata</i> <sup>T</sup>
<i>Montipora lobulata</i> <sup>T</sup>
<i>Pavona venosa</i> <sup>NW</sup>
<i>Pocillopora danae</i> <sup>T</sup>
<i>Pocillopora elegans</i> <sup>T</sup>
<i>Turbinaria reniformis</i> <sup>NW</sup>

**Figure 4.** Proportion of the observed herbivorous fish community made up by three IUCN functional group classifications.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 26/35: Achugao

Achugao is located on the north-east side of Saipan. Achugao is ranked 26/35 with a resilience score of 0.65 (anchored to 0.77) and is classified as a medium resilience site. Four of the nine variables used in the resilience analysis received high scores: coral diversity, temperature variability, macroalgae cover, and sedimentation (Table 1). Coral recruitment and sedimentation received medium scores, while bleaching resistance, herbivore biomass, and fishing access all received low scores. Coral diversity is high at the site with a Simpson's Index of Diversity value of 0.94. In addition, the site has the coral community most susceptible to bleaching of all the sites with 59.93% found to be susceptible. The substrate is made up of live coral (54.7%), pavement (bare substrate, 27.7%), and lesser amounts of algae, sand, rubble, and invertebrates (Fig. 1).

Three of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 3 species, 2 species were proposed in November 2012 as 'threatened' and 1 species was proposed as 'not warranted' (Table 2). Most of the corals at this site are larger than 16cm; a characteristic unique to this site (Fig. 2). Herbivore biomass is 0.26 kg/100m<sup>2</sup> (34/35, Fig. 3) and grazers make up the majority of the observed herbivorous fish community (Fig. 4). All of the Scarids observed were 16-20 cm in length. Acanthurids observed ranged from >5-20cm (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.94	0.97
Recruitment	9.06	0.63
Bleaching Resistance	40.07	0.45
Temperature variability	0.95	0.96
Herbivore biomass	0.26	0.08
Macroalgae cover*	0.00	1.00
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	107	0.06
Resilience score		0.65
Final anchored resilience score (26/35)		0.77

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (3/24)
<i>Acropora vaughani</i> <sup>T</sup>
<i>Acropora verweyi</i> <sup>T</sup>
<i>Heliopora coerulea</i> <sup>NW</sup>

**Figure 2.** Size-class frequency distribution for stony corals.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 27/35: Tanapag Staghorn

Tanapag Staghorn is located in the northern part of the Saipan Lagoon. This reef is a common fishing area for the community of the Tanapag village and has a resident nurse shark. Tanapag Staghorn, ranked 27/35, has a resilience score of 0.60 (anchored to 0.72) and is classified as a medium resilience site. Coral diversity, bleaching resistance, temperature variability, and macroalgae cover received high scores (Table 1). Nutrient input was the only variable to receive a medium score, while coral recruitment, herbivore biomass, sedimentation, and fishing access all received low scores.

Diversity of corals is below average (0.85) at this site (Simpson's Index of Diversity value of 0.78). The substrate is made up of live coral (48.3%) and algae (45.3%). The remaining <10% is made up by sand, rubble, and pavement (Fig. 1). Four of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 4 species, 2 species were proposed in November 2012 as 'threatened' and 2 species were proposed as 'not warranted' (Table 2). Corals range in diameter from less than 1 cm to 64 cm, but most corals are small (<8 cm in diameter) (Fig. 2). Herbivore biomass is 0.78 kg/100m<sup>2</sup> (19/35, Fig. 3). Most of the herbivorous fish community observed were grazers (Fig. 4). All Scarids observed were less than 15 cm in length (Fig. 5). Acanthurids have a wider size-class distribution and ranged in length from 5-20 cm (Fig. 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.78	0.80
Recruitment	4.88	0.34
Bleaching Resistance	82.67	0.93
Temperature variability	0.96	0.97
Herbivore biomass	0.78	0.24
Macroalgae cover*	10.67	0.85
Nutrient input*	6.59	0.76
Sedimentation*	2.57	0.51
Fishing pressure	7	0.00
Resilience score		0.60
Final anchored resilience score (27/35)		0.72

**Figure 1.** Proportion of the substrate covered by 9 groups.

## Rank 28/35: MMT Managaha Patch Reef

This site is located within the Managaha Marine Conservation Area. This is one of three sites established by the CNMI MMP. The multiple sites were chosen to replicate the wide range of habitats found in the MMCA. The MMT Managaha Patch Reef is the 28<sup>th</sup> ranked site and is classified as a medium resilience site with a resilience score of 0.60 (anchored to 0.71). Four of the 9 variables used in the resilience analysis had high scores: coral diversity, temperature variability macroalgae cover, and fishing access. One variable,

bleaching resistance, received a medium score (Table 1). Four variables received low scores: coral recruitment, herbivore biomass, sedimentation, and nutrient input. Despite the lowest score for sedimentation and one of the lowest scores for nutrient input, coral species diversity at this site was high with a Simpson's Index of Diversity value of 0.94. Turf algae makes up much of the substrate (45.3%). Live coral; sand, rubble, CCA, and pavement (bare substrate) make up 22.7%. Other invertebrates make up the remaining area (Fig. 1). Five of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 5 species, 4 species were proposed in November 2012 as 'threatened' and 1 species was proposed as 'not warranted' (Table 2). Most corals observed were small (<8 cm in diameter). A few corals with diameters larger than 32 cm were observed as well (Fig. 2). Managaha Patch Reef has a herbivore biomass concentration of 1.34 kg/100m<sup>2</sup> (10/35, Fig. 3) and a herbivorous fish community dominated by scrapers (Fig. 4). The size-class frequency of observed Scarids was much wider than that of Acanthurids (Figs. 5 & 6). Some Scarids were observed to be as large as 21-25 cm in length. All Acanthurids observed were <15 cm in length.

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.94	0.95
Recruitment	8.94	0.36
Bleaching Resistance	67.74	0.73
Temperature variability	0.96	0.96
Herbivore biomass	0.30	0.40
Macroalgae cover*	0.00	0.94
Nutrient input*	2.04	0.01
Sedimentation*	1.43	0.00
Fishing pressure	443	1.00
Resilience score		0.60
Final anchored resilience score (28/35)		0.71

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (5/24)
<i>Acropora verweyi</i> <sup>T</sup>
<i>Heliopora coerulea</i> <sup>NW</sup>
<i>Millepora tuberosa</i> <sup>T</sup>
<i>Montipora lobulata</i> <sup>T</sup>
<i>Pocillopora elegans</i> <sup>T</sup>

**Figure 2.** Size-class frequency distribution for stony corals.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 29/35: Pak Pak Beach

Pak Pak Beach is located in the southern portion of the Saipan lagoon. Pak Pak Beach is a popular swimming beach as it is adjacent to the Pacific Islands Club Resort. Pak Pak Beach has a resilience score of 0.59 (anchored to 0.70) and is a medium resilience site. This 29<sup>th</sup> ranked site has just four variables that received high scores: coral diversity, temperature variability, macroalgae cover, and nutrient input (Table 1). Sedimentation was the only variable to receive a medium score, while coral recruitment, bleaching resistance, herbivore biomass, and fishing access all received low scores.

Coral diversity at Pak Pak beach is just above the average (0.85) for the surveyed sites (Simpson's Index of Diversity value of 0.90). Live corals make up almost 50% of the benthos at this site; algae, sand, rubble, and CCA make up the remaining area (Fig. 1). Nine of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 9 species, 6 species were proposed in November 2012 as 'threatened' and 3 species were proposed as 'not warranted' (Table 2). Most corals observed at the site are small (<16 cm in diameter) (Fig. 2). Pak Pak Beach had the lowest herbivore biomass of all the sites, 0.13 kg/100m<sup>2</sup> (Fig. 3). Most of the herbivorous fish community observed at the site were grazers (Fig. 4). Scarids and Acanthurids have similar size-class frequencies with most fish <10 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.90	0.93
Recruitment	3.38	0.24
Bleaching Resistance	45.45	0.51
Temperature variability	0.95	0.96
Herbivore biomass	0.13	0.04
Macroalgae cover*	3.00	0.96
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	16	0.01
Resilience score		0.59
Final anchored resilience score (29/35)		0.70

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

Species observed (9/24)
<i>Acanthastrea brevis</i> <sup>T</sup>
<i>Acropora aspera</i> <sup>T</sup>
<i>Acropora vaughani</i> <sup>T</sup>
<i>Cyphastrea agassizi</i> <sup>NW</sup>
<i>Cyphastrea ocellina</i> <sup>NW</sup>
<i>Heliopora coerulea</i> <sup>NW</sup>
<i>Millepora tuberosa</i> <sup>T</sup>
<i>Pocillopora danae</i> <sup>T</sup>
<i>Pocillopora elegans</i> <sup>T</sup>

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 30/35: Tuturam

Tuturam is located in Laolao Bay. A natural stream drainage once flowed right through the reef, but construction of an access road changed this, causing heavy sedimentation issues for this and other parts of the Bay. Recent road and drainage improvements have been made and the natural stream has been realigned. Tuturam has a resilience score of 0.58 (anchored to 0.70) and is classified as a medium resilience site. Four of the nine variables used in the resilience analysis have high scores: coral diversity, bleaching resistance, temperature variability, and nutrient input (Table 1). No variables fell within the medium range; the rest of the variables: coral recruitment, herbivore biomass, macroalgae cover, sedimentation, and fishing access all received low scores. Coral diversity is high at the site (Simpson’s Index of Diversity value of 0.95) but this site had the highest macroalgae cover of all the sites surveyed. The substrate is made up almost entirely of algae – 82.3%, with only 8.8% live coral and lesser amounts of sand, CCA, and pavement (Fig. 1). One of the coral species originally petitioned in 2009 for endangered species status was observed during these surveys. This species was proposed as ‘not warranted’ (Table 2). Most of the corals at this site are recruits (<4 cm in diameter) (Fig. 2). Herbivore biomass at the site is 0.45 kg/100m<sup>2</sup> (29/35, Fig. 3) and the herbivorous fish community is dominated by grazers (Fig. 4). Acanthurids have a wider size-class frequency than Scarids, ranging from 5-20 cm (Figs. 5 & 6). All of the Scarids observed were <15 cm in length.

Table 1. Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

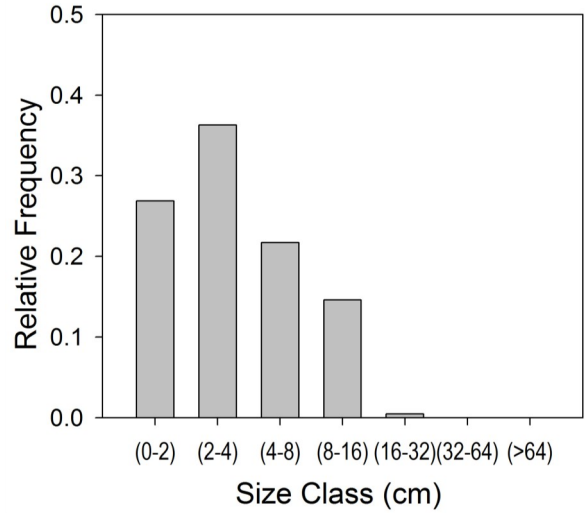

Variable	Raw Value	Anchored Score
Coral Diversity	0.95	0.98
Recruitment	8.38	0.59
Bleaching Resistance	72.17	0.82
Temperature variability	0.95	0.96
Herbivore biomass	0.45	0.13
Macroalgae cover*	72.44	0.00
Nutrient input*	4.57	0.84
Sedimentation*	2.14	0.59
Fishing pressure	614	0.35
Resilience score		0.58
Final anchored resilience score (30/35)		0.70

**Figure 1.** Proportion of the substrate covered by 9 groups.

## Rank 31/35: Tank Beach

Tank Beach is located within in the Forbidden Island Marine Sanctuary, on the exposed northeastern boundary. Tank Beach is a well documented turtle nesting site. This site is a Marine Monitoring Team survey site. Ranked 31<sup>st</sup> overall, Tank Beach has a resilience score of 0.58 (anchored to 0.69) and is classified as a medium resilience site. Coral diversity, bleaching resistance, temperature variability, macroalgae cover, and fishing access all received high scores (Table 1). Bleaching resistance was the only variable to receive a medium score. Coral recruitment, herbivore biomass, nutrient input, and sedimentation all received low scores. Coral diversity was high with a Simpson's Index of Diversity value of 0.96. The substrate at the site is made up by mostly live coral (43.3%) and turf algae (27%) (Fig. 1). Pavement (bare substrate), sand, rubble, and invertebrates make up the remaining area. Tank beach has the lowest scores of all surveyed sites for both nutrient input and sedimentation. Nine of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. Of these 9 species, 7 species were proposed in November 2012 as 'threatened' and 2 species were proposed as 'not warranted' (Table 2). More than half of the corals were very small (<8 cm in diameter) (Fig. 2). Herbivore biomass at the site is 0.26 kg/100m<sup>2</sup> (33/35, Fig. 3) and most herbivorous fish observed were scrapers (Fig. 4). All Scarids observed were 11-15 cm in length (Fig. 5). Acanthurids ranged in length from 5-30 cm with most species 11-20 cm (Fig. 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.96	0.99
Recruitment	6.13	0.43
Bleaching Resistance	68.75	0.78
Temperature variability	0.95	0.96
Herbivore biomass	0.26	0.08
Macroalgae cover*	0.35	1.00
Nutrient input*	27.72	0.00
Sedimentation*	5.26	0.00
Fishing pressure	1771	1.00
Resilience score		0.58
Final anchored resilience score (31/35)		0.69

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Table 2.** Coral species observed originally petitioned in 2009 for endangered species status by the NMFS. Proposed classifications were released in November 2012—T= Threatened, and NW = Not Warranted.

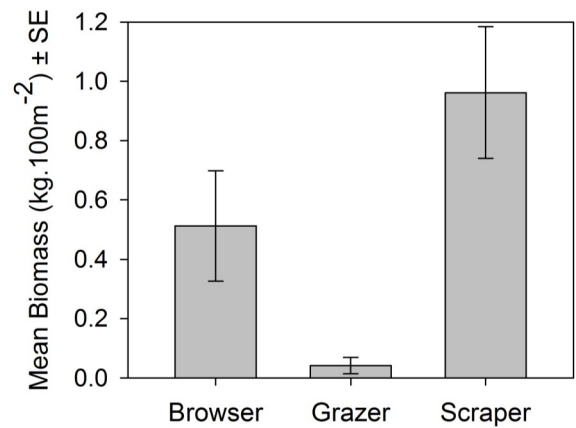

Species observed (9/24)

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 32/35: Peysonnelia Reef

This site is one of the CNMI Marine Monitoring Program's long-term survey sites. This site has been affectionately called the 'Peysonnelia Sanctuary' due to the high cover of Peysonnelia, a fleshy red algae. Peysonnelia Reef is the lowest-ranked site (32/35) considered to be a medium resilience site (0.55, anchored to 0.66). Coral diversity, bleaching resistance, temperature variability, and macroalgae cover all received high scores. Herbivore biomass, nutrient input, sedimentation, and fishing access all received low scores

(Table 1). The Simpson's Index of Diversity value is 0.79. Algae covers 71.7% of the substrate, though only 0.33% of this is macroalgae (Fig. 1). One of the coral species originally petitioned in 2009 for endangered species status was observed during these surveys. This species was proposed in November 2012 as 'threatened' (Table 2). Most corals observed at the site were very small (<8 cm in diameter) (Fig. 2). Herbivore biomass is 0.48 kg/100m<sup>2</sup> (26/35, Fig. 3). The herbivorous fish community observed was made up in nearly equal parts of browsers, grazers, and scrapers (Fig. 4). About half of the Scarids observed and almost all Acanthurids observed were less than 15cm in length; the other half of the Scarids were 16-25 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.79	0.82
Recruitment	8.56	0.60
Bleaching Resistance	85.95	0.97
Temperature variability	0.94	0.95
Herbivore biomass	0.48	0.14
Macroalgae cover*	0.33	1.00
Nutrient input*	19.95	0.28
Sedimentation*	4.47	0.15
Fishing pressure	137	0.08
Resilience score		0.55
Final anchored resilience score (32/35)		0.66

**Figure 1.** Proportion of the substrate covered by 9 groups.

**Figure 4.** Proportion of the observed herbivorous fish community made up by three IUCN functional group classifications.

**Figure 5.** Size-class frequency distribution of Scaridae.

**Figure 6.** Size-class frequency distribution of Acanthuridae.

## Rank 33/35: Marianas Resort

Marianas Resort is located within the northern portion of the Saipan Lagoon. The quaint, secluded beach has only one access point – a path from the Marianas Resort & Spa. This is a popular site with snorkelers and during our surveys a black tip reef shark was seen passing through. Marianas Resort is a lagoon site with a resilience score of 0.48 (anchored to 0.57) and is ranked 33/35. This is one of three sites considered to be low resilience sites. Only two variables received high scores: temperature variability and nutrient input

(Table 1). Macroalgae cover and sedimentation received medium scores; the remaining five variables used in the resilience analysis received low scores: coral diversity, coral recruitment, bleaching resistance, herbivore biomass, and fishing access. Coral diversity was well below the average (0.85) with a Simpson's Index of Diversity value of 0.48 and about 80% of the coral community is susceptible to bleaching. Live coral and algae each account for 43% of the substrate while sand, rubble, CCA, and pavement can be found in lesser amounts (Fig. 1). One of the coral species originally petitioned in 2009 for endangered species status was observed during these surveys. This species was proposed in November 2012 as 'threatened' (Table 2). Coral recruitment was the second lowest of all the sites surveyed and most corals observed at this site were small (<16 cm in diameter) (Fig. 2). Herbivore biomass was 0.88 kg/100m<sup>2</sup> (18/35, Fig. 3) and the herbivorous fish community observed was mostly comprised of scrapers (Fig. 4). Size-class frequencies for Scarids and Acanthurids are similar; most fish observed in these families were <15 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.43	0.45
Recruitment	0.94	0.07
Bleaching Resistance	20.00	0.23
Temperature variability	0.96	0.97
Herbivore biomass	0.88	0.26
Macroalgae cover*	22.33	0.69
Nutrient input*	2.34	0.92
Sedimentation*	1.53	0.71
Fishing pressure	7	0.00
Resilience score		0.48
Final anchored resilience score (33/35)		0.57

## Rank 34/35: Quartermaster Staghorn

Quartermaster Staghorn is located in the central portion of the Saipan Lagoon. The survey site falls just within the Lighthouse Reef Trochus Sanctuary. Quartermaster Staghorn is ranked 34th overall and with a resilience score of 0.44 (anchored to 0.53) is classified as a low resilience site. Temperature variability and nutrient input are the only variables to have received high scores with just sedimentation receiving a medium score (Table 1). Six of the nine variables used in the resilience assessment received low scores: coral diversity, coral recruitment, bleaching resistance, herbivore biomass, macroalgae cover, and fishing access.

coral diversity, coral recruitment, bleaching resistance, herbivore biomass, macroalgae cover, and fishing access. Coral diversity is very low at this site with a Simpson's Index of Diversity value of 0.10. In addition, 80% of the coral community is susceptible to bleaching, resulting the second lowest score of all sites for this variable. Live corals account for 63% of the substrate and algae for 32.3%; 3% or less of sand and rubble make up the remaining area (Fig. 1). One of the coral species originally petitioned in 2009 for endangered species status was observed during these surveys. This species was proposed in November 2012 as 'threatened' (Table 2). Most corals observed are small (<16 cm in diameter) Quartermaster Staghorn has mostly large corals with diameters >64 cm (Fig. 2). Herbivore biomass at the site is 1.42 kg/100m<sup>2</sup> (9/35, Fig. 3). The herbivorous fish observed were mostly scrapers (Fig. 4). The size-class frequencies for Scarids and Acanthurids are similar; most fish in these families observed are 11-15 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

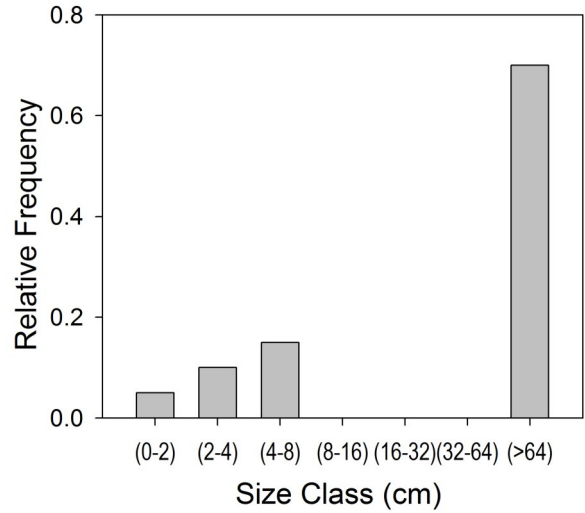

Variable	Raw Value	Anchored Score
Coral Diversity	0.10	0.10
Recruitment	1.06	0.07
Bleaching Resistance	20.00	0.23
Temperature variability	0.94	0.95
Herbivore biomass	1.42	0.42
Macroalgae cover*	32.33	0.55
Nutrient input*	2.04	0.93
Sedimentation*	1.43	0.73
Fishing pressure	10	0.01
Resilience score		0.44
Final anchored resilience score (34/35)		0.53

## Rank 35/35: Fishing Base Staghorn

Fishing Base Staghorn is located within the Saipan Lagoon. This extensive patch of *Acropora aspera* is found just off of the Garapan Fishing Base dock, where an old fisherman’s co-op was once located. Fishing Base Staghorn is the lowest ranking site with a resilience score of 0.41 (anchored to 0.49), and is considered a low resilience site (Table 1). Temperature variability, macroalgae cover, and nutrient input all received high scores while sedimentation received a medium score. Five of the variables used in the resilience

analysis received low scores: coral diversity, coral recruitment, bleaching resistance, herbivore biomass, and fishing access. Other sites may have more had more variables with low scores, however, three of these variables at this site received anchored scores of 0.00, the lowest score possible. Though coral cover at this site is 100% (Fig. 1), there is no diversity (Simpsons Index of Diversity value is 0). One of the coral species originally petitioned in 2009 for endangered species status were observed during these surveys. This species was proposed in November 2012 as ‘threatened’ (Table 2). This coral species is highly susceptible to bleaching. All corals observed at Fishing Base Staghorn were >64 cm in diameter (Fig. 2). Herbivore biomass is 0.42 kg/100m<sup>2</sup> (30/35, Fig. 3) and most of the herbivorous fish community observed were scrapers (Fig. 4). Most Scarids and Acanthurids observed were <15 cm in length (Figs. 5 & 6).

**Table 1.** Raw and anchored scores for all resilience variables, and the final resilience score and ranking for this site out of 35.

Variable	Raw Value	Anchored Score
Coral Diversity	0.00	0.00
Recruitment	0.00	0.00
Bleaching Resistance	0.00	0.00
Temperature variability	0.95	0.96
Herbivore biomass	0.42	0.13
Macroalgae cover*	0.00	1.00
Nutrient input*	2.62	0.91
Sedimentation*	1.62	0.69
Fishing pressure	13	0.01
Resilience score		0.41
Final anchored resilience score (35/35)		0.49
